facilities are used on a two-wire basis (*i. e.*, the same path for the two directions of transmission). The third system of loading, which has been used on either 16- or 19-gage wires, provides circuits for relatively short hauls only. This system of loading (known as the H-172-63) uses 172- and 63-mh. coils on the sides and phantoms, respectively, placed on 6,000-ft. spacings. A fourth loading system (B-22) not yet in place is proposed for very high-grade service in transmitting radio broadcast programs. This loading is placed on 16-gage pairs and consists of 22-mh. coils placed at 3,000-ft. intervals.

While loading decreases the attenuation of the voice current, amplification still is required at certain intervals on the longer cable circuits. This is obtained by using vacuum-tube amplifiers or "repeaters" more or less regularly spaced along the cable. The practical limit in improvements obtainable by loading, and the lower cost of relatively small wires, made economical the placement of repeaters at about 50-mi. intervals on the Los Angeles-San Francisco cable. There are three types of these repeaters which have been standardized: the first is the four-wire amplifier consisting of two independent amplifiers for the two directions of transmissions; the second is for two-wire circuits and consists of two one-way amplifiers interconnected through devices known as hybrid coils which separate the two directions of transmission; and the third type is for use on the 16-gage B-22 loaded circuits transmitting programs for radio purposes. These are high-quality amplifiers passing a very wide range of frequencies and are used for transmitting in one direction only. The shortness of the spacing between the repeater points at San Francisco and Oakland was justified for practical and economical reasons in connection with 22-gage cable in the submarine section. (Fig. 1.)

As a general rule 20-cycle current is used for signaling on the shorter cable circuits on which telegraph circuits are not superposed. For circuits more than two repeater-sections in length, 135- or 1,000-cycle signaling currents are used, depending upon the economies of the particular case. If 1,000-cycle signaling is used, it is interrupted at the rate of 20 cycles per sec., and has the advantage of passing through and being amplified by the repeaters, necessitating no equipment for relaying around the repeaters as is the case for 20- and 135-cycle current on circuits more than two repeater-sections in length.

CABLE SELECTION AND DESCRIPTION

Individual circuits in the cables are designed to provide a predetermined grade of transmission on the basis of the "general toll switching plan," the fundamental Bell System circuit arrangement used for the layout of toll plant. In instances where more than one design will fulfil the requirements the most economical one is selected.

Although it is generally desirable to install a cable with the same make-up in all sections, it was not possible in this case, because of differences in the circuit requirements and the different rates of growth along the various portions of the route. A typical cross-section of the cable used between Fresno and Los Angeles is shown in Fig. 2 where may be noted the location of the various quads and pairs contained in it, the coloring of the insulation which enables particular quads to be identified, and the system of numbering. The quads are arranged in layer formation with the 16-gage quads in the center. The twelve 16-gage broadcast pairs and the 22-gage tracer quad are interspersed in the first and third layers (counting from the outside) of 19-gage quads placed around the 16-gage section. The heavy lines are merely to aid in visualizing the segregation of the various groups in the cable and do not represent a shield or separator of any kind. The tracer quad is used for test pairs during the construction period, and for making good any bad quad in a reel length.

The cable line comprises 138 mi. of aerial cable, 270 mi. of underground cable, and, under San Francisco Bay, 4 mi. of submarine cable. To a great extent location of the aerial plant was dependent upon the terrain and the presence of high-voltage power systems. Private right-of-way routes were available in many sections and where used provide a strip of land at least 100 ft. wide. In general the cable was placed in underground conduit in principal cities and towns, and in such other places as major moves apparently would be required in the immediate future, or where, for other reasons, such construction was economical. With the exception of 18.6 mi. of fiber duct on private right-of-way south of Bakersfield, all of the underground was of clay duct. The principal sections of the route on private rights-of-way occurred between Hayward and Stockton Junction and between Bakersfield and Newhall; mountainous country was encountered in both instances, justifying the use of private rights-of-way on the basis of savings in cable mileage.

For a distance of some 34 mi. between Merced and Madera the cable parallels an 11-kv. circuit of the San Joaquin Light and Power Corporation at a separation of about 150 ft. This exposure was considered sufficiently severe to warrant some remedial measure, and a plan was developed jointly with the power company which provided for the breaking of the exposure into several sections, and the reduction of its total length by rerouting a portion of the power line. The costs of this measure were borne jointly by the two companies.

For 57 mi. between Bakersfield and Newhall the cable is carried aerially on a private right-of-way. Thirty-five miles of this is over the Tehachapi and Sierra de La Liebre Mountains, passing through some rough country. (Fig. 3.) The route was selected to be as short and direct as possible, consistent with accessibility and economy. The most desirable location leading through fairly direct canyons and passes had to be avoided because of the presence of a 220-kv. power line from which a maximum separation was desirable to avoid inductive interference. The Ridge Route highway, a scenic motor artery which in general follows the summits of the ridges, also was impracticable because of the length of its circuitous route. In these mountains elevations of 4,500 ft. are encountered where heavy snows and occasional sleet storms occur during the winter months. Hence, in accordance with Bell System standards, this section is classified as a medium-loaded area.

Among the unusually interesting construction problems encountered in this 35-mi. desolate and practically uninhabitated section were the building of about 10 mi. of construction road and nine bridges, and the widening and grading of 9 mi. of existing narrow dirt roads or paths. The nearest railroad station from which material could be hauled was Lancaster, on the Mojave desert to the east. From that point a satisfactory road extended for about 40 mi. toward the line from which point special transportation equipment was used over the construction roads. From the railroad delivery point at Lancaster, the principal items of material were transported to the job in a series of three steps: (1) 10-ton six-wheel trucks and trailers hauled the material over as much of the distance as was accessible to them; (2) then 2½-ton four-wheel-drive trucks, and (3) in some instances tractors and trailers, were used to deliver the material to its point of use.

Loading-coil cases weighing as much as 1,675 lb. were placed approximately 6,000 ft. apart and to facilitate this work and the setting of poles, special rigging often was required. Special automotive equipment for handling the reels of cable weighing up to 6,000 lb. and for digging holes, setting poles, and pulling cable was used to good advantage. Frequently because of the ruggedness of the territory and the consequent impossibility of reaching the desired locations with power equipment many of these operations had to be performed by hand.

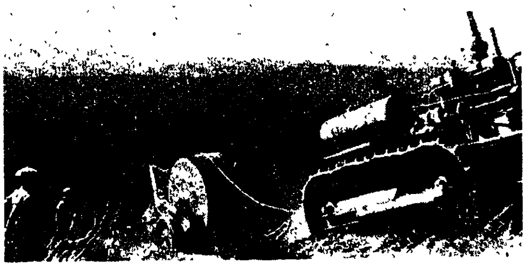

Fig. 5. A piece of typically difficult construction—lowering a reel of cable down a mountain side

PROTECTIVE FEATURES

The insulating qualities of the paper strip used for electrical separation of the conductors of a telephone cable are entirely dependent upon the exclusion of moisture. For this reason it is essential that the cable sheath be made moisture-proof and maintained in that condition. Methods which have proved valuable during the past few years make use of dry, compressed nitrogen gas, maintained under pressure within the cable sheath. A recent development is the use of continuous pressure in the cable after completion, with low-pressure alarm contactors spaced along the sheath at equal intervals. A drop in pressure in the vicinity of a contactor causes it to operate and close an alarm circuit in the cable which in turn sounds an alarm in the testing office. Gas escaping through any holes occurring in the sheath prevents the entrance of moisture for a sufficient time to permit the hole to be located and repaired. This method is in use in the fiber-duct section south of Bakersfield. The gas outfits consist of 100-cu. ft. tanks equipped with small regulating outfits which control the admission of the gas to the cable.

In general, on this job, each reel of cable was tested by injecting the gas into it under pressure after it had been pulled into place and before the sheath-ends were opened preparatory to splicing. With a pressure of 12 lb. per sq. in. throughout the cable length, any sheath opening manifested itself by a drop in pressure and was located with the aid of the hissing noise caused by the escaping gas. After each splice was completed it was tested by forcing nitrogen under pressure into it through a small hole in the sleeve, any opening being indicated by bubbles in the liquid soap with which the sleeve then was painted.

Elaborate means are taken in modern toll cables to reduce cross-talk between pairs and to reduce the picking up of noise from outside sources. The various circuit groups are kept separate, each group retaining its identity throughout each repeater section. An example of this is shown in Fig. 2 where it may be seen that the four-wire group transmitting in one direction (Group 6) is kept apart as much as possible from the four-wire group transmitting in the other direction (Group 3). The broadcast pairs are located in the four-wire group transmitting in the same direction in which they are used.

The twisted-pair and quad arrangement previously described provides the initial transposing between circuits. In manufacturing the cable, three regular types of quads are made, each differing from the other by the length required for the pair-twists, and by the length used per twist when the pairs are formed into quads. These different types of quads are used further to reduce the cross-talk between the cable circuits. To avoid the possibility of two quads in adjacent layers continuing beside each other for any particular distance, alternate layers are stranded in opposite directions during manufacture, the exact relationship between the layers shown in Fig. 2 being true only at exceptional points.

Special attention to splicing technique and splice transpositions tends to equalize or compensate for various circuit inequalities, cutting down cross-talk. Further to reduce cross-talk between two-wire circuits, at each repeater point the cross-connections are so arranged that while the phantom circuits are connected straight through, the side circuits are systematically rearranged among the quads. For the four-wire circuits a similar procedure is followed at the repeater offices which are located at the ends of circuit units. It should be noted that all these efforts to reduce the cross-talk do not result in its entire elimination, but serve to reduce it to within an acceptable limit.

Measurements and tests made on the sides and phantoms (after all the splices for a repeater section are completed and the pairs with opens, crosses, grounds, or low insulation have been cleared or tagged) include loop resistance, resistance unbalance, insulation resistance, cross-talk, transmission measurements at 1,000 cycles which are checked against calculated values, "singing-point" tests, and impedance-frequency runs on those circuits which have a poor singing point. In general, impedance runs are made on a sample of from 5 to 10 per cent of the circuits to check the correctness of loading and to locate irregularities.

BUILDINGS—EQUIPMENT—MAINTENANCE

Equipment associated with the cable is placed in eleven buildings along the route, five of which were newly constructed for the purpose and one of which, isolated in the Tehachapi Mountains, required the construction of residences for the operating personnel (Fig. 4). Equipment contained in these offices is required principally for phantoming, ringing, amplifying, and regulating purposes. Its extent may be appreciated from the fact that nearly 6,000 three-element vacuum tubes were supplied initially, although in many offices only sufficient equipment was installed to take care of a part of the circuits which ultimately will be in service in the cable.

In operating the cable, it is convenient to establish "circuit units" which consist of circuits lined up for a definite transmission value between the offices designated as "circuit-unit terminals"—San Francisco, Modesto, Fresno, Bakersfield, and Los Angeles. These circuit units are interconnected to form longer circuits, it being necessary merely to insert repeaters with the proper gain at the circuit-unit terminal offices. Each circuit unit is under the jurisdiction of a control station (San Francisco, Oakland, Fresno, Los Angeles) which is responsible for keeping it up to the required transmission standard. Test wires are set up in the cable between the various repeater points to enable each station to converse with all others as required in lining up and maintaining the circuits.

Variations in conductor resistance occasioned by daily and seasonal temperature changes may cause disturbances in the transmission losses of the various cable circuits. To compensate for this, a pilot-wire regulating system is installed in each circuit-unit section. This system consists essentially of a composited cable-telegraph circuit, or pair, known as a pilot wire, the resistance variations of which cause equipment in certain repeater stations to function and automatically compensate for variations in all circuit units. The circuits are of course lined up for average temperatures, and the regulators provide for temperature variations in either direction.

FUTURE EXTENSIONS

It is expected that future demands for toll circuits on the Pacific Coast will result in further major extensions to the long distance cable network. Among the factors which tend in this direction are: the availability of tape armored cable which may be placed directly in the ground without a subway structure; the use of automotive equipment which makes feasible the extension of heavy cable plant into rougher country; and the use of gas pressure in cables to indicate potential trouble, which makes practicable the maintenance of cables through sparsely populated areas.

These items, and others which undoubtedly will be realized in the near future, permit forecasting the extension of the coast cable network to connect the Seattle area with the Southern California area and the ultimate use of cable to connect the Pacific Coast cable network with that of the rest of the Bell System.

Engineering Progress—1731 - 1831 - 1931

The second article in The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" presented here predicts further industrial decentralization as a result of the wide availability of electric power.

By
MARTIN J. INSULL

Company, Chicago

FOR SOME peculiar reason, in comparisons of present day life with that of preceding times, it seems to be assumed that progress invariably moves in one direction only. This of course is not necessarily true. We see this clearly if we review the history of the primary factor underlying the industrial changes of the twentieth century and the two centuries which preceded it.

That primary factor is power. Our life today, with its machinery, its mass production, and its teeming cities, is an outgrowth of changes in the nature of our power resources. The rural life which it supplanted likewise was determined by the nature of the power resources of the time.

Naturally the human race's work and welfare vary according to the amount of energy at its command. If energy is limited to human and animal muscle, depending upon vegetation for its fuel, it sets certain limits on the amount of possible production. Likewise, it dictates a dominantly agricultural mode of existence. However, if energy is derived from coal and water, the limits upon production tend to disappear and the importance of agriculture diminishes.

If we examine the nature of our energy resources in 1931 and compare them with the energy resources of 1831, and of 1731, we shall see quite clearly how the form of industrial structure always has been dictated by this energy factor. And by close examination, we shall see that the direction of these changes is not always the same.

The year 1731 was one in which population was widely diffused. Why? Because it was necessary to derive from agriculture the greater amount of the energy necessary to do the world's work; and agriculture is necessarily a scattered activity. Furthermore, without mechanical power there was little incentive to develop machinery or to organize people into factory groups.

In the following hundred years violent changes occurred. Freed from the definite limitations of human energy, and with the infinite resources of the coal pit at its command instead of the meager annual crops, industrial production was multiplied. To take advantage of this greater energy supply it was necessary to concentrate production because the power supply itself was concentrated. Great cities drew population from the countryside. The countryside could spare them because agriculture no longer had to produce the entire energy supply, and because agriculture itself simultaneously became more efficient.

That trend toward concentration, when superficially considered, seems to have continued to the present day. There are, to be sure, ample evidences of it. But there are still more striking evidences to the contrary; evidences that industry is tending once more away from concentration and toward diffusion.

These changes, too, are concerned with the nature of our energy supply. By 1831 power had changed the decentralized industry of 1731 into a centralized industry; in 1931 power appears to be changing industry back into a decentralized structure. The power supply of today is widely distributed. At virtually every point on the map, electricity is available in any quantity, whereas its predecessor, steam power, was to be had at relatively few points. The same is true of transportation, which after all is only another form of power.

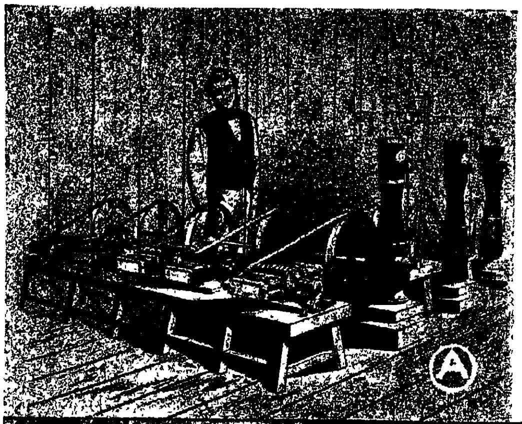
And industry is not slow to recognize the advantages of decentralization in terms of lower costs and improved working conditions. In this there is hope for those who view with despair our industrial evolution. Let them not conclude that, because we were headed toward industrial concentration for a century or more, we cannot reverse the direction of our development. We need not necessarily expect still more congested cities, still higher skyscrapers, nor a depopulated countryside. The industry of the future is more likely to reinhabit the countryside; to possess all the advantages of power machinery without the disadvantages of congestion which have hitherto accompanied it.

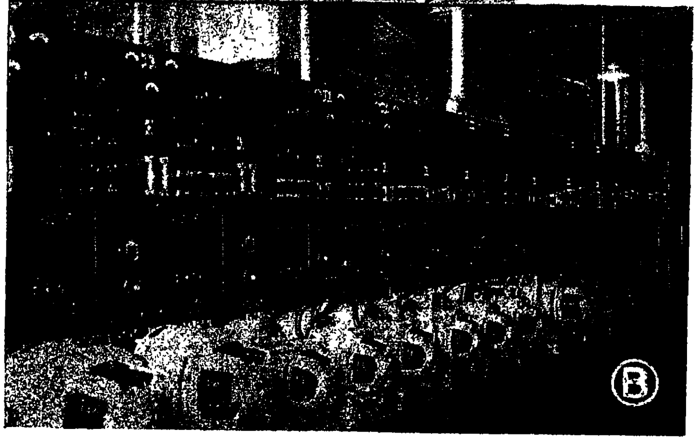
Second of series of articles written expressly for The Engineering Foundation, and released to ELECTRICAL ENGINEERING for publication. *Not published in pamphlet form.*

Editor's Note: Pursuant to the invitation of The Engineering Foundation, the editors will be happy to receive comments, suggestions, criticisms, or discussions pertaining to this or the other articles published in this series.

Power Supply for

FASTER telegraphic communication is expected in this day of increasing speed of transportation; and speed must be accomplished with accuracy and the highest degree of service continuity. In order to meet these service demands electrically-operated devices in great variety, including belt-type message conveyer and pneumatic tubes in the larger offices, are finding their way into telegraphic service in ever-increasing quantities. Thus it is that the power plant is more than ever the heart of the system and every means must be provided to maintain an absolutely unfailing supply of electric energy.



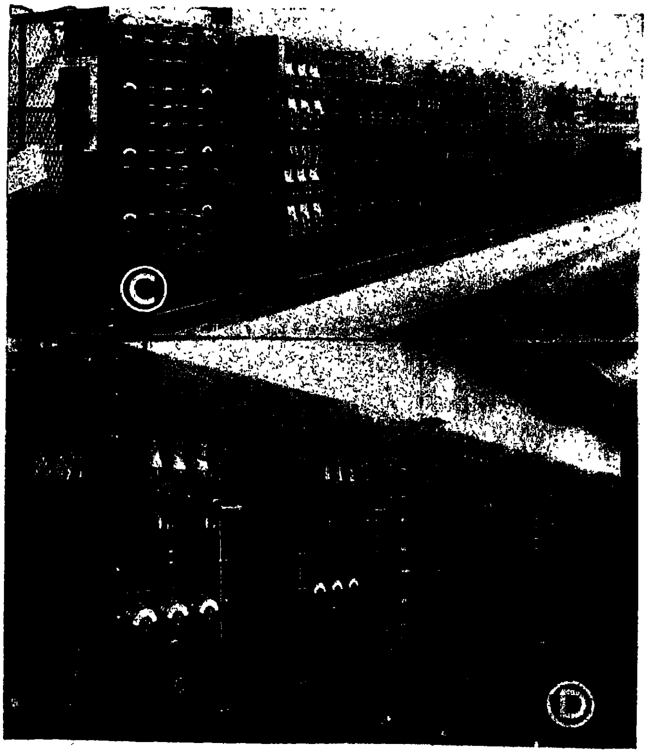


(A) In September 1880 this and two other similar steam-engine-driven dynamo groups were installed by the Western Union at 195 Broadway, New York, the first in a telegraph office. The sketch is reproduced from the *Scientific American* of January 31, 1880. Each machine delivered 40 amperes at 70 volts; four of each group in series provided potentials of 70, 140, 210, and 280 volts, with the fifth serving as an exciter. One group furnished positive potentials; one negative potentials; and the third group was a standby unit. The plant replaced 15,000 gravity cells and released 90 per cent of a 10,000-sq. ft. floor for other uses.

(B) Some of the 37 motor-generators totaling 190 hp. recently installed on the eleventh floor of Western Union's new building at 60 Hudson Street, New York, to serve 1,123 automatic and 145 Morse telegraph circuits and about 500 ticker circuits. The present maximum power demand of the New York office totals 295 kw.; 75 kw. for telegraph circuits, 50 kw. for ticker circuits, 40 kw. for belt conveyers, and 130 kw. for pneumatic tubes. For the operation of message belt conveyers, 15,722 ft. of belt and 274 small motors totaling 76 hp. are used.

(C) Distribution switchboard on the eleventh floor power room of Western Union's New York office. Duplicate sets of feeders traversing separate shafts connect this board with the telegraph board (C). On the second panel may be seen a high-speed automatic throw-over switch developed specifically to shift telegraph equipment from regular to emergency circuits upon slight potential drop in the regular circuits, and to do so without loss of synchronism in automatic equipment and circuits. The switch accomplishes the transfer from one power source to the other in less than 0.1 sec. and represents one of the most important of recent developments in telegraphic equipment.

(D) Half of the main power switchboard in the New York office basement. This section controls telegraph power including belt conveyers, compressors, a portion of the lights, emergency generating units, and the emergency storage batteries.



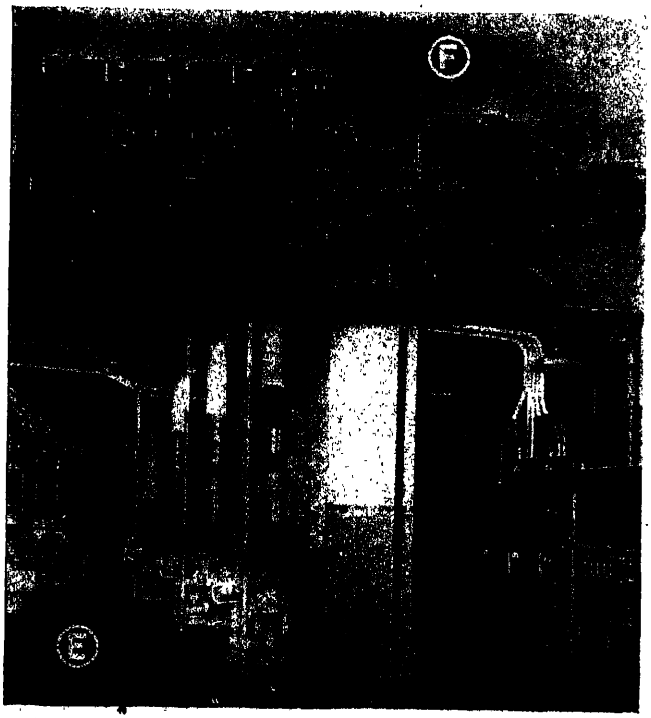
From "Telegraph Power Plants," (No. 31-62) by E. W. Griffith, Western Union Telegraph Company, New York. Presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

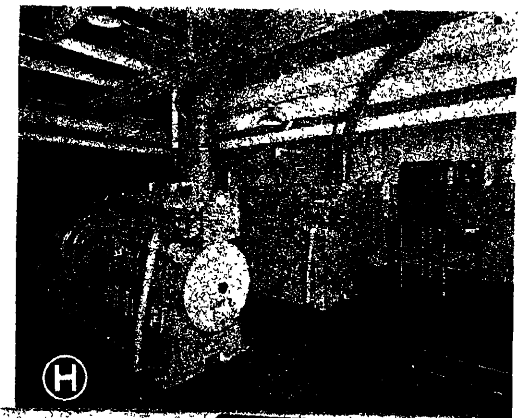
Telegraph Service

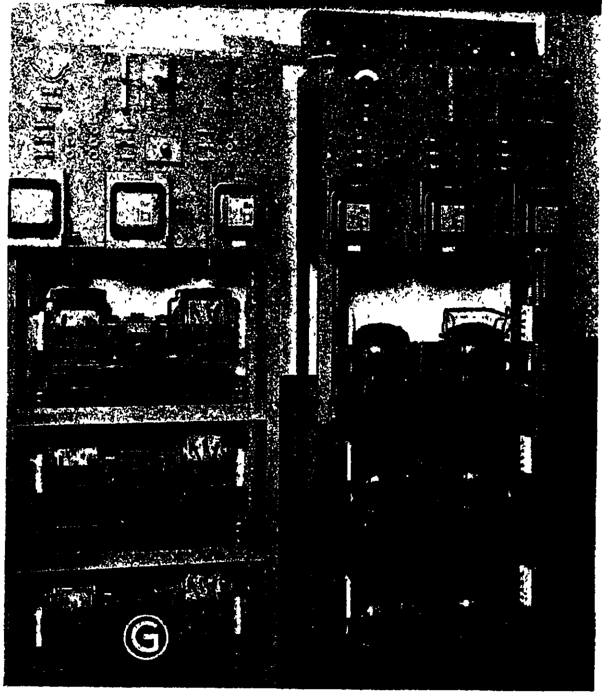
WESTERN Union policy now calls for the acquisition of power from local electric service companies instead of from private plants or batteries. This requires the use of motor-generator sets at the various offices for conversion to the desired voltages. Continuity of service is guarded by emergency engine-driven sets or storage batteries; or in the most important offices by both. At present there are about 1,085 Western Union stations equipped with a total of 4,320 motor-generator sets; 115 depend upon storage batteries for main power supply; some 450 isolated railroad stations still depend upon gravity batteries.

(E) High-speed pneumatic-tube blower installation at New York serving 50,000 ft. of tubing used for handling telegrams to 60 branch offices and 48 stations. A total of 363 hp. in blowers and compressors is required.

(F) An 8-cylinder, 200-hp., 1,200-r. p. m. gasoline-engine emergency set, typical of the new area in automotive design. The evolution of satisfactory high-speed, internal-combustion industrial-type engines and the economic advantages accruing from their use for emergency telegraph power supply have brought about some trial installations. In the new Western Union office in Boston an engine similar to that illustrated will drive a 125-kva., 208-volt, three-phase, 60-cycle alternator. It is expected to effect savings both in space required and in first cost.







(G) Motor-generators of 500-watt size and smaller generally are mounted on self-supporting steel frame "wall-type benches" specially designed to conserve space in the small offices where they are used. The sets shown are of special design, and each generator has a double commutator enabling it to serve an individual metallic circuit with 160 volts of both polarities. Switches, jacks, and cords provide for convenient transfers to meet emergencies.

(H) In some of the larger offices economies dictate two smaller emergency units instead of one larger one. The two shown are 6-cylinder, 80-hp., 900-r. p. m., gasoline engines driving 50-kva., 220-volt, three-phase, 60-cycle alternators in the Western Union's Pittsburgh office. Starting batteries and control panel may be seen in the background. All moving parts are covered and the exhaust manifolds are water-jacketed; a Maxim silencer usually is installed in the exhaust line. To decrease the transfer of noise and vibration to the building the entire sub-base is mounted on springs; and all connections, of course, made with flexible piping. In Western Union offices throughout the United States there are installed 114 emergency units; 67 gasoline, 23 gasoline (starting) and kerosene (running), 16 fuel gas, 7 semi-Diesel, and 1 full Diesel. The smallest unit is 8 hp.; the largest 120 hp.

Field Tests on Circuit Breakers

Tests show conclusively that the new high-speed oil-blast circuit breaker will clear the most severe faults within eight cycles or less, and from a system operating standpoint this type of breaker is reported as being definitely superior to other types. A careful analysis of the results shows further cause for the adoption of the multi-duty cycle. This and the two articles on the following pages outline the test procedure and discuss the conclusions reached.

CIRCUIT BREAKER field tests made during the summer of 1930 at the Philo (Ohio) plant of the American Gas & Electric Company, together with the contributions which these tests have made to the design and performance of circuit breakers are described in this article. Inasmuch as the tests involved the placing of short circuits directly on the 132-kv. bus of the largest generating plant on the entire interconnected system, before conducting such an investigation, careful consideration was given to the benefits which might be obtained.

Most prominent among the disclosures made by these tests are:

1. Circuit breaker performance.

An increased confidence in the higher ratings of circuit breakers was demonstrated. That the 8-cycle breaker has been realized was shown definitely, while in addition some progress was made toward the adoption of a multi-duty cycle. The explosion-chamber type of breaker was shown to be distinctly superior to the other types tested.

2. Circuit breaker development.

Weaknesses which now exist in the mechanical construction of the explosion-type breakers for high-speed operations but which can be corrected in future designs were pointed out.

3. System performance.

Added experience and confidence in plant operation have been provided through the large number of short circuits carried directly on the generating plant bus without apparent damage to equipment. Normally, the rate of rise of recovery voltage across the breaker contacts was found not to exceed 600 volts per microsec. System voltage dips were observed to be notably less severe when the high-speed explosion-chamber breaker was being tested than when testing the other types.

System connections for these short-circuit tests are shown schematically in Fig. 1. It may be noted that practically the entire interconnected system of the American Gas & Electric Company's group, together with some of the more important outside interconnections, were tied together in a practically normal set-up. With such an arrangement a short circuit of over 1,500,000 kva. was provided at the Philo bus, the major portion of which was supplied by the Philo plant itself.

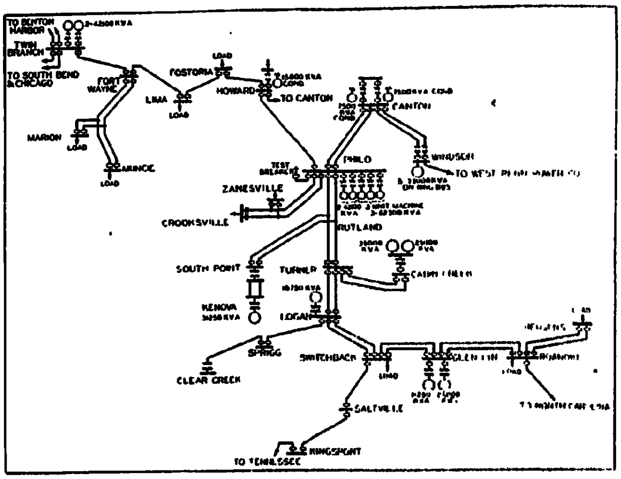


Fig. 1. System connections for the 1930 Philo 132-kv. circuit-breaker tests

In order that the tests might be carried out to take advantage fully of the entire 1,500,000 kva., a standard breaker of that rating with a 60-in. tank was used. This was mounted on a concrete mat foundation immediately adjacent to the 132-kva. Philo switchyard (see Fig. 2) and was connected to the bus by short overhead 250,000-cir. mil copper conductors.

TEST PROCEDURE

The first group of tests consisted of 28 shots on the breaker equipped with standard butt-type explosion-chamber contacts. Of these, 7 were made with the Philo generators alone supplying the short-circuit current and with no transmission lines connected to the short-circuited bus; 4 of these 7 were made with full plant capacity; 5 shots were made with the maximum available system capacity and undoubtedly resulted in a duty on the circuit breaker either at or more than its full rating.

The second series of tests consisted of 40 shots on the same breaker equipped with the new oil-blast explosion chamber and contacts (see Fig. 3). These new explosion chambers have been described in previous publications (see *The Oil-Blast Circuit Breaker*, by D. C. Prince and W. F. Skeats, ELECTRICAL ENGINEERING, Feb. 1931, Vol. 50, p. 134). These tests included a total of 16 shots with the maximum rate of recovery voltage and with no lines connected to the bus. In 7 of these 16 shots full capacity of the Philo plant was connected to the bus thus providing short circuits of from about 1,000,000 to 1,285,000 kva. Six shots were made with the maximum available system capacity, all of which as in the previous case imposed full rated duty or more upon the breaker.

The third and final group of tests consisted of 13 shots only, the tests having been cut short on account of a broken bushing on the breaker used as a closing breaker for opening shots on the test breaker. In these final tests the same breaker was used but was equipped with the older type of segmental contacts and explosion chambers. Six shots were made at intervals of from ¾ to 1½ min. with light duty and rates of recovery-voltage rise; the succeeding 6 shots were made at intervals of from 1 to 3 min. with the maximum available system capacity. The final shot, which originally was intended to be the first of a series, was made with full capacity of Philo plant and with the medium rate of rise of recovery voltage obtained with one short line connected to the short-circuited bus.

In all tests the rate of recovery-voltage rise was varied to suit by connecting or disconnecting lines to Philo generating station bus. By such manipulation three rates of recovery-voltage rise were obtained: namely, 270, 600 and 2,400 volts per microsec.

Test Results and System Performance

By
PHILIP SPORN American Gas & Elec. Co., New York
Fellow A. I. E. E.

H. P. St. CLAIR American Gas & Elec. Co., New York
Member A. I. E. E.

SYSTEM DISTURBANCES due to the tests were not serious and caused but little trouble and but few complaints except from consumers at points nearby. Recording voltmeters were installed during the tests at all of the important 132-kv. substations on the system. Typical charts from these recorders are shown in Fig. 4. While inertia and overtravel in a voltmeter of this type are responsible for some of the variations in the charts, nevertheless a clear comparison may be noted between the severity of disturbances caused by high speed and by ordinary circuit breakers. The most striking comparison is revealed by the charts obtained at points close to the Philo plant, such as those taken at Crooksville. Here again the inertia of the moving pen instrument plays a large part in the record obtained, but at the same time a fairly accurate comparison may be drawn. In addition it is felt that a dip, the duration of which is too short for the recording voltmeter pen to follow, may also be too short to cause a synchronous machine to fall out of step.

SUMMARY OF IMPORTANT RESULTS

In general the principal objects for which the tests were undertaken were quite fully realized. The manner in which the tests will prove of real benefit from the standpoint of system performance is indicated in the following listing:

1. 2,500,000-kva. breakers now feasible.

In view of the fact that a test breaker equipped with a 60-in. tank successfully interrupted a 1,735,000-kva. short circuit, there is little doubt

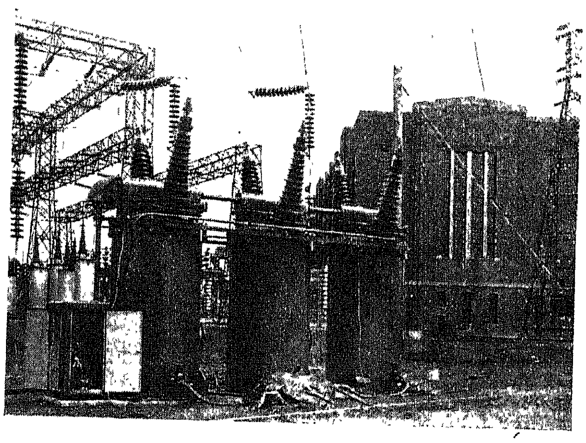

Fig. 2. The 132-kv. 1,500,000-kva. oil circuit breaker with 60-in. tank used in the tests. Note proximity to substation and power house structures

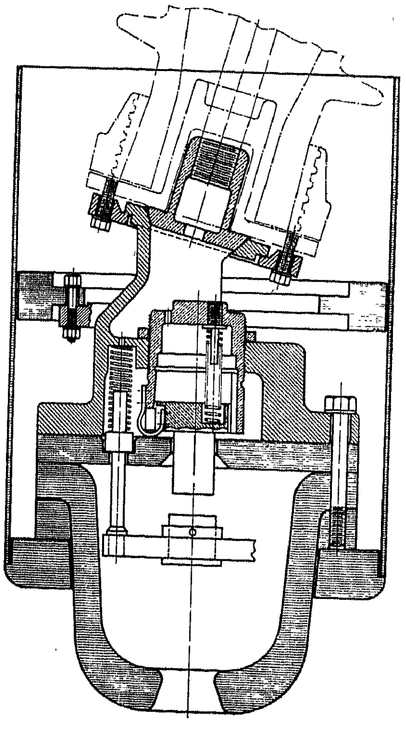

Fig. 3. Circuit breaker explosion chamber with new oil-blast contacts

---

From "Oil Circuit Breaker Tests—Philo 1930, Aims, Set-Up and Results from a System and Operating Viewpoint," (No. 31-25) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

but that standard breakers with 72-in. tanks will operate satisfactorily under their rated duty of 2,500,000 kva. This positive assurance is of value, in that it enables the engineer to plan system expansion along the most desirable lines without being hampered by fears of circuit-breaker limitations.

2. The 8-cycle breaker a definite realization.

All short circuits in tests on the new oil-blast explosion chambers and contacts were cleared in 8 cycles or less. High-speed breaker operation will greatly accelerate the clearing of a faulty line, which is particularly important where two or more parallel lines are being protected. It is also valuable for preventing a complete loss of voltage on one of two interconnected systems by quickly clearing the interconnecting tie when the load approaches its static-stability limit.

3. Increased confidence in plant performance.

Ability of the generating station equipment to withstand these heavy short circuits without apparent damage has proved beneficial in the training and experience of the operating personnel at Philo; a greater degree of confidence in plant performance has resulted.

4. Adoption of the multi-duty cycle predicted.

Definite progress for the adoption of the multi-duty cycle for circuit-breaker performance has been realized through a demonstration of the ability of the breaker to handle successively a large number of heavy short circuits without intermediate inspections or changes of oil.

5. Design defects were revealed.

Two explosion-chamber failures occurred during the course of the tests. These were caused apparently by the general weakness of the chambers and not by other faults of design. It is believed that subsequent changes in design will prevent a recurrence of such failures.

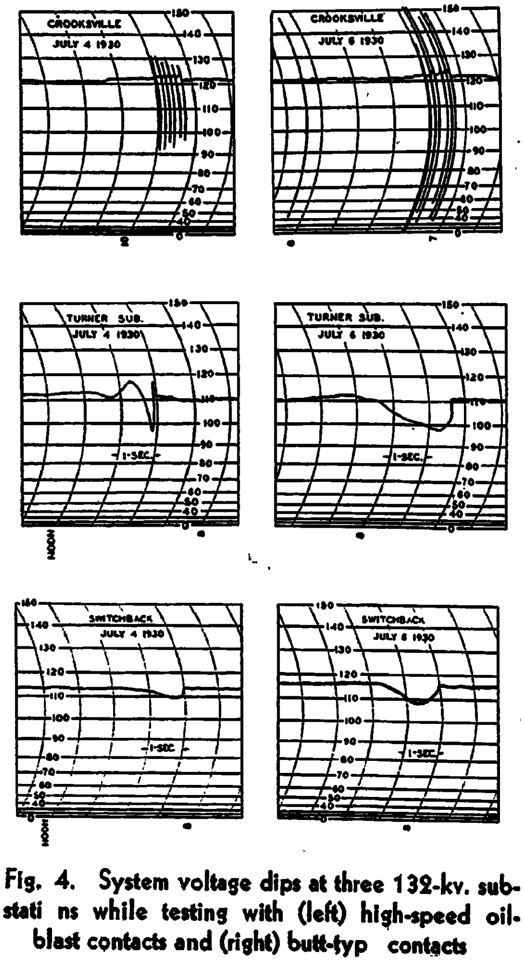

Fig. 4. System voltage dips at three 132-kv. substations while testing with (left) high-speed oil-blast contacts and (right) butt-type contacts

Test Results and Circuit Breaker Behavior

PERFORMANCE of different types of breaker contacts, and rates of recovery-voltage rise, are the principal items receiving particular attention in this analysis of the Philo circuit breaker tests. As stated previously the rate of recovery-voltage rise was manipulated by varying the number of lines connected to the Philo station bus.

In the 28 tests made with the butt-type contacts, the kva. interrupted ranged from 268,000 to 1,640,000. The range of short-circuit duration was from 7.5 to 39 cycles, while breaker operating time varied from 7 to

From "Circuit Breaker Field Tests on Standard and Oil-Blast Explosion-Chamber Oil Circuit Breakers," (No. 31-26) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

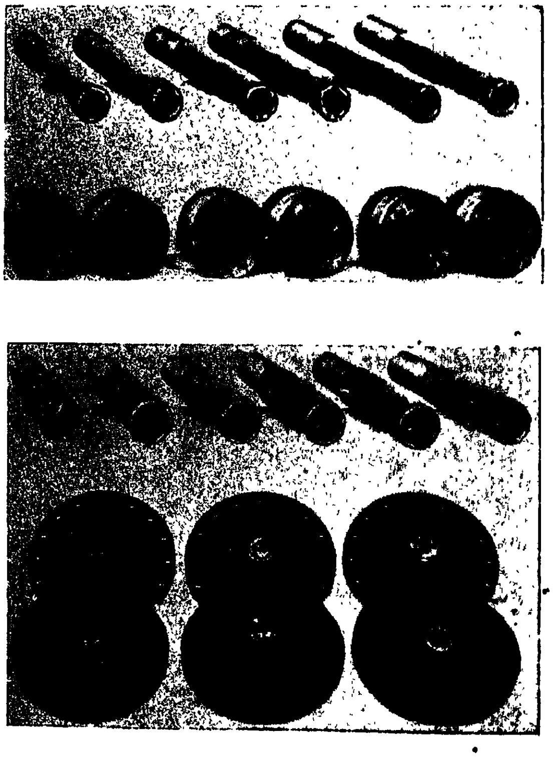

Fig. 5. Condition of contacts after tests. (Above) butt contacts after 28 tests; (below) oil-blast contacts after 40 tests

38 cycles. Arc duration ranged from 4.5 to 36 cycles; arc length from 11.5 to 32 in. Maximum tank pressure recorded in this series of tests was 36 lb. per sq. in., while the average was 10 lb. Although slight mechanical difficulties were encountered they were not of a fundamental nature and will be corrected quite readily by minor changes in design. Although these butt-type contacts were somewhat burned after the tests, as may be seen in Fig. 5, their condition was such that they could have been kept in operation for many more tests.

SUPERIORITY OF NEW EXPLOSION-CHAMBER CONTACTS

Results of the 40 tests made with the hollow-type contacts operating in the new type oil-blast explosion chamber the kva. interrupted ranged from 177,000 to 1,735,000. The short-circuit duration varied from 5.5 to 9 cycles, and breaker operating time from 4.5 to 8 cycles. Arc duration varied from 1.6 to 5.7 cycles, while arcs from 2.5 to 14.5 in. were recorded. On the last six tests of this group, all in excess of 1,500,000 kva. and made at intervals of about two minutes, the average tank pressure was 8 lb. per sq. in., the maximum being 11 lb. The condition of these contacts after test may be seen also in Fig. 5. Actual measurement indicated that a total of less than ¼ in. of contact metal had been burned away from the arcing surfaces. In order to determine their suitability for further operations, these contacts were returned to the factory and subjected to a heat run using twice the breaker-current rating; the resulting temperature rise was less than 30 deg. cent.

In the third series of tests with the segmental-type contacts, 7 tests ranging in value from 940,000 to 1,400,000 kva., were made in 10 min. Short-circuit duration varied from 12 to 18 cycles, corresponding breaker operation ranging from 11 to about 15 cycles. Arc duration varied from 4.5 to 7.2 cycles; arc length from 11.3 to 14.8 in.

A comparison between the performance of the butt-contact breaker and that of the oil-blast contact breaker is shown in Table I. Effects of the rate of recovery voltage rise upon arcing time and arc lengths may be noted quite readily. Average arc duration for the butt-type contacts was 8.6 cycles as compared with 3.5 cycles for the oil-blast contacts. A comparison between arc lengths shows an average of 18 in. for the butt contact and 6.8 in. for the oil-blast contact. Average contact-opening speed for the oil-blast breaker was 9.5 ft. per sec. as compared to 13 ft. per sec. for the butt contact.

TABLE I—PERFORMANCE COMPARISON FOR BUTT AND OIL-BLAST BREAKER CONTACTS

Butt Contacts

Lines connected to bus	Calculated volts per microsecond	No. of tests	Av. arc duration cycles	Av. arc length in.
3	270	17	6.2	15.5
1	600	4	7.1	17.0
0	2400	7	15.0	24.5
Total 28 tests	Average		8.6	18.0

Oil-Blast Contacts

Lines connected to bus	Calculated volts per microsec.	No. of tests	Av. arc duration cycles	Av. arc length in.
3	270	15	2.6	4.5
1	600	9	3.7	7.1
0	2400	16	4.1	8.8
Total 40 tests	Average		3.5	6.8

CONCLUSIONS

After a careful analysis of the test results, the following conclusions seem justified:

1. Rate of recovery voltage rise affects to some extent the interrupting performance of the breaker.
2. Standard breakers now available commercially will operate satisfactorily on the highest rates of recovery-voltage rise now encountered (about 600 volts per microsec.).
3. The oil-blast breaker has demonstrated a distinct superiority over the other types of breakers tested.
4. Standard oil-blast breakers now available commercially possess an over-all operating time of 8 cycles or less.

The Orient Turns to Automatic Telephones

By
Y. K. CHOW
Member A. I. E. E
Hangchow, China

MANY great poets of China repeatedly have described the beauty of Hangchow. It is the capital of the Province of Chekiang, one of the smallest but richest in the country. At one time its leading glory was the fame of its beautiful landscape, but the town now is winning a standing also through the increasing application of modern engineering. Among several developments the most recent and perhaps most important is the new automatic telephone exchange system which now serves the whole area.

Only a little more than twenty years ago telephone development was started by commercial enterprise in this ancient capital; subsequently the system was transferred to a government organization. A little later again to become a commercial enterprise; present

---

developments are being made by the Provincial Government. In the early days telephone service was not in the general demand that it is today; hence growth and development came slowly. Also, financial difficulties and the lack of suitable technical study caused the design and growth of the system to be governed largely by expediency. Subsequently the age of the switchboard and other equipment, and the poor condition of the line plant, prohibited any major attempt for modernization without complete system reconstruction.

In 1927 the Provincial Government decided to construct a network of long distance telephone lines to link together all the cities in the province, and to connect also to Nanking and Shanghai. Since that time toll service has grown rapidly, with a consequent expansion in the problem of improving local service in the Hangchow area. Meanwhile, the city's telephones had increased gradually until there were five magneto-type exchanges scattered over the whole area, the largest of which had a capacity of 1,200 lines. Early in 1929 the government completed its plans for taking over the existing exchanges from the operating company and invited bids for system rehabilitation from leading telephone manufacturers throughout the world.

In addition to the economic questions that had to be settled in connection with such a major undertaking, there were the problems of language difficulty, training and maintenance of staff and operators, and the ever-present matter of public opinion. Ultimately the rotary-type of machine-switching system was adopted as best suiting the service requirements, as well as satisfying economic limitations.

The present equipment consists of one 2,700-line exchange with a building and power plant which provides for an ultimate of 5,000 lines, and one 300-line exchange designed and equipped for an ultimate of 500 lines. The existing manual exchange in the south of Hangchow will be converted shortly to automatic operation. Also it is hoped that conversion of the rural exchanges to automatic operation may be carried out in the near future.

Radiotelephone Service is Expanding

With 91 per cent of the world's telephones already provided with facilities for direct international conversations, plans and developments are progressing to provide extensions. Present services are outlined here and some data given covering the Hawaiian link now under construction.

American Tel. & Tel. Co., New York

SINCE January 7, 1927, when commercial radiotelephone service first was established between New York and London, continuous and important developments have been made in the application of radiotelephony to intercontinental communications. Also, there has been a generally sustained increase in the public demand for this class of service to the end that today the Bell System in cooperation with the British Post Office has four radiotelephone circuits to London, the original long-wave channel supplemented by three short-wave channels. By means of these, telephone subscribers in the United States, Canada, Cuba, and Mexico may be connected to practically any telephone in Europe, in the city of Ceuta, Northern Africa, in part of Australia, and in Java, Dutch East Indies.

Service to all European points and to Ceuta is furnished through London where connection is made to the submarine cables and land line facilities making up the European telephone network. As yet Russia, Greece, Turkey, and a few of the Balkan States cannot be reached from the United States over this network. Service to Australia is given by switching the New York-London radio circuits at the latter point to a short-wave radiotelephone channel between London and Sydney. Service to Java is furnished through London to Amsterdam or Berlin, where connection is made to a short-wave radio channel operated between those points and Java by the Dutch Telephone Administration.

Transatlantic telephone messages between the United States and Europe during the first six months of 1931 were about 20 per cent greater than for the corresponding period for 1930. While the basic rate, which is the rate from New York to London for a 3-min. period, was reduced from $45 to $30 on May 11, 1930, the increase in traffic is considered very satisfactory in view of the general business conditions which have

---

existed on both sides of the Atlantic, and is an indication that this service continues to be of increasing usefulness to the public.

In December 1929, a ship-to-shore short-wave radiotelephone service was established on a commercial basis through New York with the steamship "Leviathan." Since that date service has been opened with five more of the larger liners plying between North America and various European ports, the "Olympic," "Homeric," "Majestic" the "Belgenland," and the "Empress of Britain." While at present this service is furnished normally only to ships in the Atlantic area, contacts were made last winter with the "Belgenland," during a large part of its cruise around-the-world, and with the "Homeric" then cruising in the Mediterranean.

The Bell System, in cooperation with the International Telephone and Telegraph System, established on April 4, 1930, a short-wave radiotelephone channel between New York and Buenos Aires. Through Buenos Aires, service may be given by land line connections not only to other parts of the Argentine Republic, but also to the great majority of telephones in Uruguay and Chile.

Construction has been completed recently to the end that the South American service could be enlarged to include Rio de Janeiro, Brazil. Plans for the radiotelephone system to work with Rio de Janeiro were on a basis somewhat different from those for the services heretofore established from the United States, and it may be of interest to outline briefly the arrangements made. The previously established services contemplated the full-time use of one or more complete radiotelephone circuits whereas service to Rio de Janeiro was planned on the basis of sharing facilities already provided for service to Buenos Aires.

In the United States the transmitter operating with Buenos Aires was provided with an additional antenna directed toward Rio de Janeiro; and at the receiving station there was installed a complete new receiving unit adjusted to receive from Rio de Janeiro. At the transmitting station, switches were provided for the rapid transfer of the transmitter from one antenna to the other, while at the receiving station the two receiving units serve to enable the New York control office to keep in constant touch with both distant transmitters. This arrangement permits the maximum use of equipment and facilities and seems to offer a promising means of providing for the extension of radiotelephone service to a number of points to which it may be desirable to furnish service, but where the cost of apparatus for full-time channels cannot at the time be justified. This arrangement offers also an opportunity to reduce the number of frequency assignments required, because a number of points may be served from one transmitter using the same transmitting frequencies where the conditions permit. It is expected that this general method will find considerable application in economically extending existing services. One set of transmitting equipment, which is the expensive item, can be used for service to a number of points to the extent permitted by traffic loads, by merely providing the necessary antennas and receivers.

The radiotelephone services established to date and previously referred to, now make possible the connection of telephone users in this country to more than 91 per cent of the world's telephones. From the map shown in Fig. 1 it may be seen that these existing facilities provide the ground work for furnishing telephone service from North America to the East and South. Preliminary studies have been made of the possibilities, probable demand, and usage of telephone service from the United States to all parts of the world. A worldwide service of this kind is something that is extremely interesting to contemplate, but it is obvious that while considerable progress has been made in establishing such a service, an objective of this magnitude must be approached with due consideration to such factors as equipment and antenna development, costs, probable usage, differences in time and languages, and availability of satisfactory wavelengths.

In line with the desired objective of extending service where practicable, plans have been completed recently and construction work is now in progress to establish in conjunction with the Imperial and International Communications, Ltd., a short-wave radiotelephone channel between New York and Hamilton, Bermuda,

there to connect with the land line facilities serving the Bermuda Islands. This radio circuit in general will closely resemble the other short-wave radio circuits previously established. The transmitter will be considerably smaller and of lower power, however, (500 watts unmodulated carrier outputs compared to 15 kw.) since the distance to be covered is only about 700 mi. compared to about 3,400 mi. between New York and London, 4,800 mi. between New York and Rio de Janeiro, and 5,300 mi. between New York and Buenos Aires. It is expected that the Bermuda system will be ready for operation late this year.

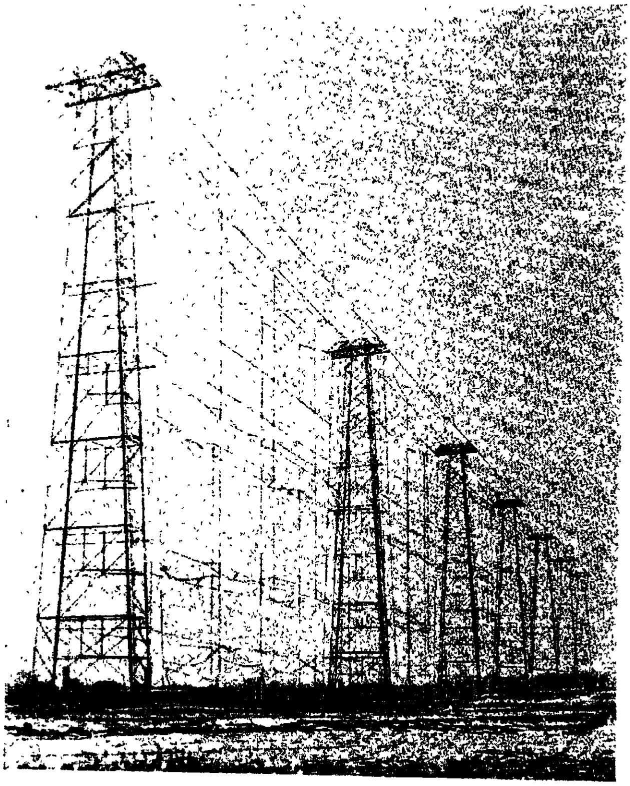

Fig. 3. Antenna towers and curtains of the type used for South American and transatlantic service

During the past 1½ years right-of-way has been acquired and two test antennas have been constructed at Bradley, Maine, near Bangor. These test antennas were constructed for experimental purposes looking forward to supplementing the existing New York-London long-wave circuit now working at 60 kc. with an additional long-wave circuit operating at 68 kc. These antennas have proved effective at Bradley, and plans now are in progress for the construction of a new long-wave transmitting station at that point. The receiving station for the additional long-wave circuit is planned for Houlton, Maine, the receiving point for the existing long-wave circuit. Owing to the magnitude of this undertaking it is expected that about three years will be required to construct the new long-wave system.

In the Pacific area the points which in the future might logically be furnished with direct radiotelephone connection with the United States include the Hawaiian and Philippine Islands, Japan, China, Australia, New Zealand, and Alaska. A transpacific short-wave radiotelephone system is now under construction, joint arrangements having been made with the Mutual Telephone Company of Hawaii to set up the initial circuit from California to Hawaii.

The transmitting station for the transpacific service is being established at Dixon, Calif., in the Sacramento Valley about 20 mi. southwest of Sacramento and the receiving station, at Point Reyes, Calif., on the Pacific Coast about 35 mi. north of San Francisco. The Dixon site contains about 640 acres and the Point Reyes site about 520 acres. These sites were selected after a rather extensive survey of the west coast of the United States during which consideration was given to avoiding, for receiving station purposes, areas too near radio transmitting stations and other sources of interference and, for transmitting station purposes, areas too near radio receiving stations. Consideration was given also to obtaining for both stations tracts of land of reasonably flat contours, free of mountain ranges which subtend angles of more than 2 or 3 deg. with the horizontal in the directions of transmission or reception. It was necessary that both sites be economically accessible for telephone, power, and transportation facilities.

The transmitter building at Dixon, a 40 x 60-ft two-story brick-and-concrete structure, is designed to accommodate two equipments although only one will be installed initially. In general, the transmitter is similar to those at Lawrenceville, N. J., consisting of several individually and carefully shielded units mounted side by side. These units include a two-stage audio-frequency amplifier, a modulator, a piezoelectric quartz crystal oscillator with two harmonic generators, and a two-stage radio-frequency power amplifier. The output of the two-stage audio-frequency amplifier is used to modulate the plate voltage of the modulator unit which contains two 250-watt tubes in a push-pull circuit. The modulator receives its carrier frequency direct from the second harmonic generator which in turn is fed by the first harmonic generator and the crystal oscillator.

The crystal oscillator is contained in an electrically heated oven the temperature of which is carefully regulated to 50 deg. cent. ± 0.05 deg. This arrangement holds the transmitted carrier frequency constant within very narrow limits. The output of the modulator unit then is applied to the grids of the two-stage radio-frequency amplifier. The first stage contains two 10-kw. water-cooled tubes and the second stage contains six. These tubes are arranged in push-pull circuits and the entire system is carefully balanced to ground. The unmodulated carrier output power of the last-stage amplifier is about 15 kw. which, under conditions for 100 per cent modulation, is equivalent to 60 kw. at the peak of the modulation cycle.

From the transmitter the radio-frequency energy is fed over an open-wire transmission line to the transmitting antenna about 800 ft. south of the building. This initial transmitting antenna for the Hawaiian service is of the horizontal double-V type (Fig. 3) recently developed by the Bell Telephone Laboratories. This type of antenna is a diamond-shaped structure consisting of one or more horizontal elements supported on wooden poles, the longer axis pointing toward the desired receiving station. The antenna is driven from the rear apex of the diamond and when suitably terminated at the opposite end, has a good unidirectional characteristic. This antenna has another very desirable characteristic in that, within certain limits, it is effective over a range of frequencies. For transmitting to Hawaii the initial antenna is designed to handle two frequencies in the vicinity of 7 and 14 megacycles. While varying somewhat with the frequency being transmitted, the gain of this antenna as compared to a single-element half-wave vertical antenna ranges from 8 to 16 db.

Comparison of the details revealed in Figs. 2 and 3 will indicate the relative simplicity, and consequently the relative economy, of the horizontal double-V antenna. This is even more strongly indicated when it is considered that in the vertical type shown each antenna occupies two spans between the 185-ft. steel towers, and that each antenna is effective for only the one frequency for which it was designed. The development of this relatively inexpensive antenna is of particular significance at this time because, if radiotelephone service is to be opened to points which do not justify the provision of individual channels, the number of antennas for use with existing equipment may be expected to increase materially in the next few years.

At the Point Reyes receiving station the building is a one-story 26 x 40-ft. semi-fireproof structure of reinforced concrete designed to house several radio receivers and their associated power and voice-frequency apparatus. However, the initial installation comprises a single receiver made up of individually shielded units. It employs two stages of screened-grid radio-frequency amplification, a first detector, an intermediate-frequency amplifier with input and output filters, a second detector and an audio-frequency amplifier. From the output of the intermediate-frequency amplifier a part of the received energy is diverted, put through a special two-stage intermediate-frequency amplifier, rectified, and supplied to the automatic gain control which in turn tends to keep the receiver output volume constant by controlling the bias potential on the radio-frequency amplifier and the first-detector grid circuits. In this receiver the first two panels which contain the equipment up to and including the first stage of intermediate frequency amplification are duplicates. By means of a switch the equipment in either of the first two panels may be connected to the rest of the receiver. This arrangement makes it possible to switch from one frequency to another with only slight tuning adjustments and therefore with the minimum loss of time.

The receiving antenna is similar in construction to the transmitting antenna already described. It is about 500 ft. northeast of the receiving building and is designed to receive two frequencies, 16,195 kc. and 7,535 kc. Connection to the receiver is by means of a concentric-conductor transmission line run underground at a depth of about 18 in. This type of line is used because of its low transmission loss at high frequencies and because of the shielding effect of the grounded outer conductor. The outer copper tubing is of 1⅝-in. outside diameter while the inner copper tubing is of ⅜-in. outside diameter. Spacers are of Isolantite.

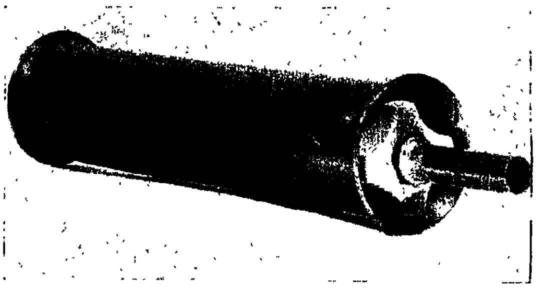

Fig. 4. Section of concentric copper transmission conductor for connecting the receiving antenna t the radio receiver

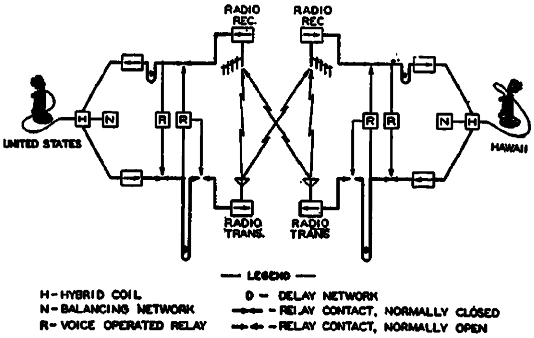

Fig. 5. Fundamental arrangements of voice-operated devices for the transpacific radiotelephon circuit

At San Francisco the terminal control equipment will be located on the first floor of the Pacific Telephone and Telegraph Company's Grant Avenue toll building. To this location are brought the transmitting and receiving radio circuits, as well as the interstation communication and order wires. Equipment at the terminal station is the same as that installed at New York for the transatlantic services and which has been described in a paper previously presented.

From the terminal control room the radio circuit is carried to a special position at the San Francisco toll switchboard where connection may be made to land line circuits extending to all parts of the country.

It is expected that service to Hawaii will be available commercially early in 1932. To the people of Hawaii the establishment of this service will offer for the first time a regular telephone connection with the North American Continent. In addition, it will afford opportunities to make tests and obtain actual field data leading to still further extension of radiotelephone communication to such other transpacific points as may be decided upon in the future.

Voice Training on a Scientific Basis

TRANSMITTING, recording, reproducing, and amplifying of sound by mechanical, electrical, and photographic devices have brought an industrial need for an exact science of sound. In 10 years of research with modern instruments and laboratory methods, and with the latest knowledge of physiology, enough has been learned to establish principles for training a voice understandingly although much additional research is needed.

Hundreds of tests were made upon voices, trained and untrained; for example, an investigation of the expulsion of breath during phonation. The singer put on a French gas mask; in its eye-piece was a telephone transmitter; rubber tubing went from the mask to a spirometer and to the air. Flutter valves allowed breathing in from the outer air and out into the spirometer, but stopped escape into the outer air or out of the spirometer. The specially designed transmitter was connected to a special amplifier and thence to an oscillograph. The singer sang several tones on different vowels at various pitches and intensities, each tone held 8 to 12 sec. Readings of the volume of air expelled per second were taken.

Observation of great singers has shown that they never produce a "dead," steady tone except at pianissimo. The tone fluctuates in intensity with perfect regularity. This fluctuation, very wide at high intensity, is accompanied with a slight fluctuation of pitch. This vibrato is the result of an impulse periodically applied to all the muscles which coordinate in the act of phonation. Its frequency is about six per second, but can be increased. Thus all the time the singer is phonating he actually is alternately singing and silent, rapidly and regularly. As the intensity rises the "on" impulse is more vigorous and the swing of the vibrato increases. Since at mezzo forte, when the technic is good, the intensity of the tone should increase as the pitch rises nearly up to the top of the singer's range, the vibrato should increase in amplitude as the scale is ascended. The vibrato decreases as the intensity drops until a point is reached at which a stream of air actuates the vocal cords, when it disappears altogether. This concept of an "on" and "off" impulse is very different from the old notion of steady control of a stream of breath.

A great voice is not due to anatomical peculiarities but to mental and emotional capacity and tractability. The human voice is a sound-producing instrument governed by the laws of sound and of physiology; it consists of a motive force (the *pressure* of the breath), a vibrator (the vocal cords), and a resonator (a set of adjustable cavities in the head and throat). Voice starts in a mental concept which brings the necessary muscles into action. A singer must have a mental concept of the pitch which he is about to sound. If this concept, or the receiving mechanism of the ear, be faulty, a pupil cannot be made to sing, although his speaking voice may be trained. Two groups of muscles, one of seven and the other (far stronger) of two, bring the vocal cords into tension and hold them there. When a mental concept initiates the nerve impulses supplied to the larynx, these muscles come into action and the vocal cords are set to the proper length, tension, and position. If the singer starts from pianissimo, where the breath pressure is at a minimum, and increases the intensity and therefore the breath pressure or the amplitude of the vibrato to fortissimo, the muscles must take on additional tension. The lighter muscle group should take tension to a point at which it would overload; then tension of the stronger group must be increased.

So long as the vocal cords are held in tension against pressure of the breath by means of additional tension on the lighter muscles, the singer or speaker is using the "upper register" (falsetto); as soon as the stronger muscles start to take on added tension, he is using the "lower register." *Registration* provides the proper method of controlling the *intensity*, not the pitch. The registers should be isolated and trained separately; only when fully developed should they be coordinated. Improper coordination of the laryngeal muscles accounts for the partial or total loss of voice of most of the great singers at an age at which they should be in their prime.

From "breath expulsion-intensity" curves, a person trained in this new science will be able to make an accurate technical criticism of a voice without having heard it. The "breath control" doctrines, long ac-

---

From *ResearchNarratives*, June 15, 1931, published by The Engineering Foundation, 29 West 39th Street, New York, N. Y. Based upon information contributed by Douglas Stanley, M. S., Assoc. City Guilds of London Inst., Fel. Acoustical Society of America, N. Y.

cepted, are fallacies. Tremolo is caused by a fluttering of the walls of the resonating cavities. The vibrato is the means for moving the voice correctly from tone to tone; it allows the singer to keep perfect time and rhythm; it can be improved and controlled by training.

The range of every properly produced voice should be at least three octaves; some persons may attain nearly four. Faulty registration and resonance adjustment can curtail the range 50 per cent or more; also reduce the power to an incredible degree. The mouth should not be used as a resonator. When a person is phonating the muscles used in the act of phonation should not be relaxed but in proper tension balance.

There is no fundamental difference between the singing and speaking voices except in so far as vowels are more sustained in singing. There is no vibrato in speech. In singing the intensity is far greater (thus the general pitch is far higher), the range far wider, and articulation much stronger than in speech. In speech, low tones are most effective; hence all normal speech should be in the pure lower register.

Abstracts

Of Papers Presented at the Pacific Coast Convention

INTERPRETIVE abstracts of all papers presented at the Pacific Coast A. I. E. E. convention (August 25-28, 1931) are presented herewith, only excepting those papers already published in this or preceding issues of ELECTRICAL ENGINEERING. Members vitally interested and wishing to obtain immediately pamphlet copies of any of these papers are requested to use the order form appearing on p. 770 of this issue. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

Electric Power In the Wood-Products Industry

By C. E. Carey[1] and K. L. Howe[1]

For references to business affiliations see listing on page 756.

THIS paper deals with electric power in those industries in the Pacific Northwest which use forest wood as raw material for manufacture. It covers briefly the electric power requirements of these industries, and presents some statistics as to electric power consumption. During the past two decades the electric energy consumed in the lumber, pulp, and paper industries of this district has grown to a value comparable to the total amount generated by all of the central stations operating within the same geographic area.

General information concerning the types of motors used for various operations is given, along with some statistical information as to average power requirements for certain machines and illustrations of typical installations. The paper deals with the general application of electric power within the wood-products industry, and does not cover the technical requirements of each of the motor applications.

The methods of manufacturing within the various plants, and the requirements of the various processes determine the extent to which electric energy is used in these various mills. The success of electric power utilization is indicated, however, by an annual energy consumption of more than 2,000,000,000 kw-hr. **(A. I. E. E. Paper No. 31 M 1)**

Electrical Equipment for Oil-Field Operations

By H. C. Hill[2] and J. B. Se Legue[2]

IN THE application of electricity to the work of drilling for oil and pumping the wells, many problems peculiar to the oil industry have been encountered. This paper presents some of the more interesting features of these applications, and is confined to a discussion of the duty involved and of the design of the apparatus for the purpose. Although the petroleum industry still relies largely upon engine power, strides have been made during the past ten years in the development and application of electrical apparatus, and in the extension of central station power into oil fields. Oil companies are giving an increasing amount of attention to its use.

A comparison is made between the methods and equipment involved in cable-tool drilling and rotary drilling. Briefer consideration is given to well-pumping control equipment, electrical protection measures, and the air-gas lift. The many other uses for electric power in oil production and handling are considered as beyond the scope of this paper.

Electric power for oil-field operations was first used in the eastern fields more than 30 years ago, but the extensive use of this form of power did not begin until 10 or 12 years later, when it was introduced in the California fields. Most of the new developments which since have been made in the design and use of electrical apparatus for oil-well drilling and pumping have been tried out and perfected first in the California fields before being adopted elsewhere. This has been due not only to the field conditions encountered there, but also to the availability of dependable central station power service in all of the fields.

Of the tremendous connected horsepower in the oil industry in the United States, it is understood that only 7 per cent is electrical. In California alone there is 1,500,000 hp. installed, of which only 15 per cent is electrical. This indicates the potential possibilities for electrification. (A. I. E. E. Paper No. 31-128)

Correlation of Induction-Motor Design Factors

By Vaino Hoover[3]

AN ANALYSIS of stator resistance, wire size, horsepower rating, and air-gap density as a function of the flux per pole per unit-length of lamination stacking, stator slot shape and slot insulation, rotor diameter, and flux densities in the stator teeth and core, is given in this paper.

The usual method of design is to begin with the rotor radius, flux per pole, and ampere-conductors per inch of rotor circumference. The flux density in the air-gap is determined when the stator-tooth density and the ratio of slot pitch and tooth width are set. The depth of slot is determined by the ampere-conductors per inch, and the cir. mils per ampere. The depth of stator core and the stator radius then are determined by setting the value of the flux density in the stator core. The relations of the rotor and stator radius, the width of slot and tooth, the depth of slot and core, the flux per pole, and the flux density, to each other and to the motor performance are quite vague. Therefore, to determine their best proportions is difficult unless many experimental data are available.

In this paper an attempt is made to determine the relation of these factors to each other, and to determine their proportions for the best design. Briefly outlined, the analysis is presented as follows: The area of the stator slot is developed as a function of the shape of the slot, and the area occupied by the slot insulation. The effect of the slot insulation on the net area of the stator slot is taken into account by using a corrected value for the stator radius. The area of the wire used for stator coils is developed as a function of the flux per pole. The stator resistance is expressed as a function of flux per pole, and slot shape. The rotor radius is determined by setting the ratio of the flux densities in the core and teeth. A sample calculation is made using this method of design for motors of from two to twelve poles. The maximum torque as a function of the flux densities and of the flux per pole is discussed. The effect of stator resistance on maximum torque is calculated and shows that the flux per pole used should be very nearly that for minimum stator resistance. Fifty-three equations are developed. Power Transmission and Distribution from the Mokelumne River Development

By E. M. Wright[6] and B. D. Dexter[6]

ESSENTIALLY the full text of this paper is published on pp. 713-18, of this issue of ELECTRICAL ENGINEERING. (A. I. E. E. Paper No. 31-131)

Tie-Line Control of Interconnected Networks

By T. E. Purcell[6] and C. A. Powel[7]

OPERATING experience with tie-line load regulators on the Pittsburgh, Pa. tie line interconnecting the Colfax Power Station of the Duquesne Light Company with the Springdale station of the West Penn Power Company is described in this paper. Equipment used, including tie-line load regulators, program load control, and a hydraulic speed changer also is described.

The prime requirements of a successful tie-line load regulator are that it must not respond to small transient load changes, but that it must respond to small sustained changes. Further, it must respond to large load changes whether temporary or sustained.

The program loading equipment mentioned is installed at the Colfax station to maintain the most economical division of load between the various generating units of that particular station. The principle of dividing all load increments proportionally between units in a steam station does not necessarily make for maximum efficiency. In the program equipment at Colfax load scheduling is based on turbine valve position rather than on generator output, thus maintaining each turbine at its most efficient valve opening regardless of the effect of the many variables which enter into the position of the valve with reference to the load.

The new hydraulic speed-changing device described is intended to reduce to a minimum, wear on the governor parts, and to offset the tendency for increased wear arising from the extremely frequent governor operation imposed by frequency control.

As a result of tests made jointly by the Duquesne Light Company and the West Penn Power Company, the following conclusions are reached:

1. Tie-line load regulators and program loading equipment have been developed to a commercial stage.
2. Tie-line load regulators on one system can be operated satisfactorily in conjunction with frequency regulators on a connected system.
3. Tie-line control may be used to reduce load fluctuations between interconnected systems. (A.I. E. E. Paper No. 31-127)

Tuned Power Lines

By H. H. Skilling[8]

Electrical Measurements of Sound-Absorption

By A. L. Albert[13] and W. R. Bullis[13]

PRINCIPALLY because of the recent development of high-quality radio broadcasting, group address systems, and sound motion pictures, the acoustic characteristics of buildings are now an important factor of architectural design. Using the work of Sabine and others as a basis, it is possible to design studios and auditoriums to give complete acoustic satisfaction.

However, since the sound-absorbing properties of various acoustic and building materials differ widely, it is necessary to determine quite accurately the sound-absorbing coefficients before reliable reverberation calculations can be made. These coefficients have been measured previously by various means, two of which are widely used. The first of these consists of covering the inner surface of a specially constructed room with the absorbing material to be tested. The sound-absorbing coefficients then can be calculated from the measured reverberation time. The other method is very similar except that instead of covering the surface of a room with the absorbing material, the material is placed on large panels in the room. Both of these methods as well as others which have been devised are accurate but necessitate the use of large test samples and are somewhat slow and expensive in use.

This paper describes an electrical method of measuring the sound-absorption properties of acoustic materials. Both the equipment and method can be said to be simple and rapid in operation, and inexpensive. With this method, the sound absorbing properties are determined by the effect produced on the electrical characteristics of a loud speaker by sound waves reflected from the absorbing material. The test equipment includes a relatively small wooden tube inside of which a loudspeaker with a special mounting may be moved back and forth with respect to the end of the box in which is mounted the sound-absorbing material to be measured. In addition to this equipment there is simply a vacuum-tube oscillator with bridge measuring arrangement including the loudspeaker coil in one side of the bridge circuit.

Advantage is taken of the generally known fact that the electrical impedance measured between the terminals of a telephone receiver or loudspeaker is greatly affected by the location of the device with respect to reflecting surfaces in front of it. The effects of various sound-absorbing materials, as reflected through the adjustable loudspeaker device, are translated through the bridge readings into comparable figures which reveal the relative characteristics of different samples of materials. Although the tests which have been made and which are described in the paper indicate that this method gives consistent results, it is believed that the device can be made even more satisfactory and perhaps arranged to give the sound-absorbing coefficients directly as an indicating-instrument reading rather than from the impedance-bridge settings. (A. I. E. E. Paper No. 31 M 6)

Cathode Drop in Arcs and Glow Discharges

By S. S. Mackeown[3]

THE ARC is defined as an electrical discharge in a gas or a vapor in which the cathode drop is of the order of 10 or 20 volts and the current density to the cathode spot is of the order of hundreds or thousands of amperes per square centimeter. For an arc to exist it is necessary that there be some mechanism for producing electrons at or near the cathode. Unfortunately, there is no general agreement among physicists as to the mechanism which produces this low cathode drop with the correspondingly high current density which is characteristic of an electric arc. In this paper the author reviews briefly the different prevalent theories regarding the low cathode drop in an arc, offering discussions and interpretations based upon extensive research work carried out at the California Institute of Technology.

The author divides his subject treatment into four general parts: (1) the cathode drop in an arc, (2) the normal cathode drop in a glow discharge, (3) the abnormal cathode drop, and (4) transition from a glow discharge to an arc. In each case prevalent theories are briefly presented and discussed. (A. I. E. E. Paper No. 31 M 5)

The Kindling of Electric Sparkover Based on Lichtenberg Figures

By C. E. Magnusson[14]

THE MECHANISM of the electric sparkover process lately has become a much discussed problem. Townsend's theory of the formation of electric sparkover has been challenged and at least in some respects found wanting. Several well-known investigators have given ample evidence that the sparkover process is very complex; that the speed of formation is in the order of 10^8 cm. per sec. instead of 10^4 or 10^5; that polarity and shape of electrodes, ionization, space charges, voltage gradients air pressure, temperature, and other factors enter into the problem. The results of investigations on the early stages of electric sparkover throw light on certain phases of the initial or kindling stage of an electric spark formation, but a comprehensive explanation of the mechanism or process involved in the formation of electric sparks or sparkover still is lacking.

In this paper a new method of approach is described and experimental evidence is presented which tends to show that for *impulse sparkover* the following statements are valid:

1. Electrons are primarily the active elements in the kindling mechanism.
2. Lichtenberg figures form the initial step in the kindling process.
3. Sparkover develops from the tips of the positive Lichtenberg figures along the streamers of both the positive and the negative figures. (A. I. E. E. Paper No. 31-123)

Snow Surveys and Hydro-Forecasting

By H. P. Boardman[15]

A COMPREHENSIVE description of the apparatus and methods involved in a cooperative precipitation survey and the results obtained are given in this paper. The scope of the paper is limited principally to the watershed area of the eastern Sierra Nevada range of California, the runoff from which constitutes the chief source of water supply for Reno, Nevada, and environs. Statistical information is presented which reveals the accuracy of predictions based on snow surveys, as compared with actual runoff for various seasons. (A. I. E. E. Paper No. 81 M 4)

Radio Coordination

By C. C. Campbell[5] and H. N. Kalb[16]

THE AUTHORS' experience with radio-interference problems in northern and central California is used as a basis for this paper. An attempt has been made to present the various phases of the problem rather than to offer a solution of any particular phase. Radio interference from natural static and from radio sources is not within the scope of this paper, but is mentioned where it has a bearing upon interference caused by electrical sources. Natural static is less severe in the West than in the East, making other types of radio interference more apparent. A larger network of higher voltage transmission lines also has been built up in the West because of the extensive hydro-electric developments and a more scattered population, and this factor also enters the problem to some extent.

Variations of broadcast service area arising from station power and location and as affected by the topography of the surrounding country have been found to have an important bearing upon the radio-interference problem. Experience shows that there is no simple solution for the interference problem; that it must be dealt with in a spirit of cooperation by the utilities, the electric manufacturers, and the public. In the West, interference from electric power supply systems is well in hand except for the troubles originating on high-voltage lines. Although filters on power lines have been suggested, their use is questionable.

Manufacturers have a great opportunity in the sale of radio noiseproof appliances and apparatus, and the public can help by insisting upon such appliances. Increased broadcast coverage is very desirable to offset the maximum noise level in many of the large areas now having low field strengths. However, continued cooperative effort on the part of all concerned undoubtedly is the best solution to the interference problem. (A. I. E. E. Paper No. 31-122)

Calorimeter Measurement of Stray-Load Losses

By G. D. Floyd[17] and J. R. Dunbar[18]

THIS paper covers several thermal or calorimeter tests which were made at the Queenston generating station of the Hydro-Electric Power Commission of Ontario, on a 55,000-kva. generator having an enclosed system of ventilation. The objects of the tests were to determine stray-load losses on short circuits and under rated load, and to obtain some information regarding the accuracy of this method of test. Descriptions are given covering the general method followed and the actual tests as made. For those who might wish to check the calculations in detail the actual figures are given in an appendix.

The results of the tests show that the stray-load losses on large units can be determined with fair accuracy by this method when an enclosed system of ventilation is used on the unit. Tests also seem to show that the difference between the stray-load losses under load conditions and under short-circuit conditions is slight, and that a test under load conditions is justified only when an extremely accurate determination of losses is required. For most purposes a test under short-circuit conditions seems to be sufficient. (A. I. E. E. Paper No. 31-126)

Bagnell dam and semi-outdoor power house of the Union Electric Light and Power Company (St. Louis) built by Stone & Webster Engineering Corporation

South West District To Meet at Kansas City

A VARIETY of interesting technical subjects, good entertainment and profitable inspection trips to noteworthy local engineering projects comprise the program for a three-day fall meeting of the South West District No. 7 to be held at Kansas City, Mo., Oct. 22-24, 1931. Headquarters will be at the Kansas City Athletic Club.

Nineteen papers will be presented in four technical sessions the first of which consists of a group of selected subjects: back-fires in rectifiers, surge tests on a distribution substation, overvoltages due to dropping of load, computing currents in networks and loops, building-construction welding, effect of wave form on relay operation, and pilot-wire relaying. The second session will be devoted to the St. Louis-Bagnell interconnection, with the showing of a motion picture description of the actual construction of the Bagnell dam. The third session will deal with communication subjects; economic surveys, advance planning of long distance telephone facilities, tape-armored cable, and the time factor in transmission. The closing session will be on subjects in the field of transmission and distribution, such as lightning field investigation, heat flow from cables, corona energy loss, fuses, and cut-outs.

The banquet Friday evening, October 23, will be held in one of the finest banquet rooms in the Middle West—that at the Kansas City Athletic Club, noted for its excellent cuisine. Between courses, entertainment will be provided by some of the best talent obtainable, and following the banquet there will be dancing with music furnished by an orchestra well qualified to please all.

Golf will be arranged for all those who may wish to play.

WOMEN'S ENTERTAINMENT

Women attending will be entertained with a luncheon bridge at one of our golf clubs, a theater party, and shopping tours. Nothing will be left undone to mak their visit to Kansas City a pleasant one.

Tentative Program

Thursday—a. m.

Registration

Opening address

Student technical session

Thursday—p. m.

(a) **Student Session**

(b) **Session on Selected Subjects**

Electric Arc Welding in Building Construction, P. N. Vinther, Dallas Power & Light Co.

The Effect of Wave Form on the Operation of Induction-Type Relays, P. H. Robinson, Houston Lighting & Power Co.

The Telegraphic Pilot-Wire Relay System, O. H. Frier, Oklahoma Gas & Electric Co.

Calculating Load Division in Distribution Systems, C. T. Almquist, The University of Oklahoma.

Back-fires in Mercury-Arc Rectifiers, J. Slepian and L. R. Ludwig, Westinghouse Elec. & Mfg. Co.

Overvoltages on Transmission Systems due to Dropping of Load, E. J. Burnham, General Electric Co.

Impulse-Voltage Tests on a 4,800-Volt Distribution Substation, H. W. Collins and E. E. Piepho, Detroit Edison Co., and J. J. Torok, Westinghouse Elec. & Mfg. Co.

Thursday Evening

St. Louis-Bagnell Interconnection

Interconnection of the 25- and 60-cycle Systems of the Union Electric Light & Power Co., E. L. Hough and L. V. Nelson, Union Elec. Light & Power Co.

Automatic Control for Variable-Ratio Frequency Converters, E. K. Shively, Union Electric Light & Power Co., and G. S. Whitlow, General Electric Co.

Three-Reel Motion Picture of the Actual Construction of the Bagnell Dam.

Friday—a. m.

Communication

Economic Surveys and Their Application to Engineering Problems, J. N. Holsen, Southwestern Bell Tel. Co.

Advance Planning of Long Distance Telephone Facilities, O. C. McFarland, Southwestern Bell Tel. Co.

Tape-Armored Telephone Toll Cable, C. W. Nystrom, Southwestern Bell Tel. Co.

The Time Factor in Telephone Transmission, O. B. Blackwell, American Telephone & Telegraph Co.

Friday—p. m.

Inspection trips and recreation

Meeting of board of directors

Friday Evening

Banquet and entertainment

Saturday—a. m.

Transmission and Distribution

Field Investigation of Lightning Disturbances on Transmission Lines, D. C. Jackson, Jr. and R. W. Warner, University of Kansas.

Heat Flow from Underground Electric Power Cables, L. J. Neuman, The Texas Co.

Corona Energy Loss, W. D. Weidlein, Black and Veatch.

Application of Primary Distribution Fuses, F. E. Sanford, Union Gas & Electric Co.

The Expulsion Fuse, J. Slepian and C. L. Denault, Westinghouse Elec. & Mfg. Co.

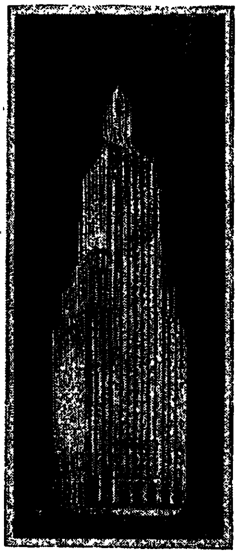
Fuse Cut-outs with Special Reference to Their Design and Application for A-C. Distribution Circuits, E. G. Newton, General Electric Co.

Saturday—p. m.

Inspection trips and recreation

Hotel Reservations

Reservations for hotel rooms should be made by writing directly to the hotel preferred. In the following table, rates are listed for the headquarters hotel, the Kansas City Athletic Club, and several other hotels conveniently located in the neighboring vicinity. Members of the Dallas, Houston, Oklahoma City, and Wichita Athletic Clubs may enjoy reciprocal relations:



New building of the Kansas City Power & Light Company features a 13,200/199/115-volt, three-phase, four-wire, vertical distribution system

Hotel	Hotel Rates Single Rooms	 Double Rooms
Kansas City Athletic Club	$3.00-$5.00	$5.00-$7.00
Baltimore	$1.50-$2.00*	$2.50-$3.00*
	$2.50-$5.00	$3.50-$6.00
Muehlebach	$2.50-$3.50*	$4.00-$5.00*
	$3.50-$8.00	$5.00-10.00
Phillips	$2.50-$4.00	$4.00-$6.00
Pickwick	$2.50-$4.00	$3.50-$6.00
President	$3.00	$5.00
Stats	$2.00-$3.50	$2.50-$5.50

*Rooms without bath

Committees

The personnel of the general committee consists of: G. C. Shaad, *chairman*, vice-president South West District; R. W. Warner, secretary South West District; S. T. Blaisdell; J. E. Busher; C. B. Fall; C. D. Farman; D. C. Jackson, Jr.; F. J. Meyer; J. S. Palmer; A. A. Rall. Subcommittee chairmen are: R. L. Baldwin, *hotels and registration*; M. M. Boggess, *finance*; D. D. Clarke, *technical sessions*; D. W. Ellyson, *golf*; G. Fiske, *entertainment*; A. L. Maillard, *inspection trips*; O. P. Minnick, *publicity and attendance*; F. L. Phillips, *transportation*; M. P. Weinbach, *student activities*.

Inspection Trips

Kansas City is the home of nearly every type of industry that can hold the attention of an engineer, especially electrical engineers. Some interesting features to be studied are the new supersynchronous motor installations for the cement mills, the completely automatic system of the Kansas City Power & Light Company, the application of electricity to the milling industry, for example the new automatic installations of the Southwestern Bell Telephone Company. Engineers interested in the application of electricity to water supply systems also will find Kansas City a capital place to study.

Grand Avenue Station

In 1927, the Kansas City Power & Light Company acquired the old Grand Avenue Station of the Kansas City Public Service Company (the street railway company). This plant which was first put in service in 1903 was antiquated and expensive to operate; however, the location made it not only favorable for central power production and distribution, but ideal as a production center for the continually increasing demand for central district steam heat. Upon the acquisition of this property, a rebuilding program was started which has extended over a four-year period and has involved the expenditure of nearly $6,000,000. The result has been the conversion of an obsolete inefficient station into a strictly modern, efficient, high-pressure power and heating plant. All central station men will want to review this rebuilt work and see how increased efficiency was brought about in so short a time.

Other Points of Interest

In addition to its two generating stations, Kansas City for its size probably has the most complete automatic power distribution system of any city in the United States, with all power except for 13.2-kv. primary service supplied from substations equipped with complete automatic control. The system consists of two major parts: the d-c. substations, and city a-c. substations with outdoor a-c. suburban stations.

The d-c. system embraces a restricted district in the downtown business section, with d-c. network fed from five synchronous converter substations of two automatically controlled machines, each of which feeds an individual bus, being tied together only through the d-c. network.

The a-c. system consists of seven 13,200/4,400/2,550Y-volt, three-phase, four-wire automatic substations. These stations located in various parts of the city are architecturally designed to conform to the type of district in which they are located. Interior designs follow usual practise, but with such additional features as comply with latest ideas. Stations of interest in this group are: Substation *R* of residential type using reinforced concrete for switch barriers and regulator bays; Substation *A* of residential type using "Ha-dite" concrete barriers; and the latest Substation *H* located in a newly developed business and apartment district, with the station exterior designed to conform with the general architectural plan of the district. The interior design is in artistic agreement with the exterior. Special features of this station include switch structures and regulator bays of fabricated stone, all circuit breakers frame-mounted and not supported by the barriers, and a heating and ventilating system fully automatic in its operation.

A visit to the Bell Telephone building will afford an opportunity to inspect a large telephone power plant, a large telegraph repeater station, a panel-type dial central office, a large manual central office, toll and local operating rooms, etc. The Benton-Chestnut exchange which is to go into operation October 1, 1931 has the most modern type of dial equipment, together with associated operators' positions. This exchange has 16,500 terminal stations with an average of 120,000 originating and 117,000 incoming calls per day.

The committee has arranged a trip to the Bagnell water power project of the Union Electric Light & Power Company located in the center of the state. This trip, in addition to the fine papers on this subject, will give an interesting picture of this much discussed project.

Radio Newspaper.—A daily newspaper, specially prepared for radio facsimile transmission by the Schenectady *Union Star*, has been sent daily to ships at sea from General Electric's short wave station at Schenectady, N. Y., since July 30. The newspaper is compiled late in the afternoon to contain the latest news of the day, and is transmitted between 9 and 11 o'clock at night over apparatus developed by Dr. E. F. W. Alexanderson (F'20). At present reception of this radio newspaper is limited. Receivers have been installed by the Radio Marine Corporation on two transatlantic liners, the *America*, and the *Minnikahda*, and another is being operated in Doctor Alexanderson's department in the General Electric research laboratory, about 3 mi. from the transmitter. The receivers are known as the carbon facsimile recorders, developed a year or two ago by Charles J. Young, son of Owen D. Young.

Tahoe Convention To Be Reported

The Pacific Coast convention at Lake Tahoe, California, opened its sessions Tuesday morning, August 25, too late to be reported in this issue of ELECTRICAL ENGINEERING. However, brief interpretative abstracts of all Tahoe papers may be found on pp. 753-56 of this issue.

The general news story covering convention activities will appear in the October issue. It is hoped also that the written discussion of Lake Tahoe papers will be in the hands of the secretary of the meetings and papers committee at 33 West 39th Street, New York, N. Y., in sufficient time and in sufficient quantity to warrant the presentation of a review of discussion in connection with the convention story in the October issue.

Directors Meet at Institute Headquarters

The regular meeting of the A. I. E. E. board of directors was held at Institute headquarters, New York, August 4, 1931. Present were: *President*—C. E. Skinner, East Pittsburgh, Pa. *Vice-presidents*—H. P. Charlesworth, New York, N. Y.; L. B. Chubbuck, Hamilton, Ont.; W. E. Freeman, Lexington, Ky.; W. B. Kouwenhoven, Baltimore, Md.; I. E. Moultrop, Boston, Mass.; G. C. Shaad, Lawrence, Kans. *Directors*—A. B. Cooper, Toronto, Ont.; J. E. Kearns, Chicago, Ill.; J. Allen Johnson, Buffalo, N. Y.; A. E. Knowlton, New York, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; C. E. Stephens, New York, N. Y. *National treasurer*—W. I. Slichter, New York, N. Y. *National secretary*—F. L. Hutchinson, New York, N. Y.

The minutes of the directors' meeting of June 24, 1931, were approved.

Approval was given to a report of a meeting of the board of examiners held July 29, 1931; and upon the recommendation of that board, the following actions were taken upon applications pending: 18 Students were enrolled; 51 Associates were elected; seven Members were elected; 23 applicants were transferred to the grade of Member and two to the grade of Fellow.

Approval for payment by the finance committee of monthly bills amounting to $38,414.61 was ratified.

Authorization was given for the extension of territory of the Los Angeles and the San Francisco Sections in order to include the entire state of California between the two Sections.

The president announced the appointment of committees and representatives for the administrative year beginning August 1, 1931. (A list of committees and representatives appears elsewhere in this issue.)

As required by the by-laws of the Edison Medal committee, the board confirmed appointments to the committee made by the president as follows: D. C. Jackson, chairman for the year beginning August 1; E. B. Meyer, L. T. Robinson, and P. H. Thomas, for terms of five years each; C. E. Stephens to fill vacancy for the year ending July 31, 1932. Also, the board elected from its own membership to serve on the committee for terms of two years each, J. E. Kearns, W. S. Lee, and F. W. Peek, Jr.

In accordance with the by-laws of the Lamme Medal committee, the board confirmed the following appointments by the president: B. A. Behrend, A. M. Dudley, and J. C. Parker.

Local honorary secretaries reappointed for the two-year term beginning August 1, 1931, were: M. A. Chatelain, Russia; A. F. Enstrom, Sweden; A. P. M. Fleming, England; T. J. Fleming, Argentina; Renzo Norsa, Italy; P. H. Powell, New Zealand; F. M. Servos, Brazil.

Upon the recommendation of the standards committee, various subjects were referred for consideration to the electrical standards committee of the American Standards Association, and approval was given for publication as a report of the committee on electrical machinery for further study by those interested, of a proposed test code for transformers prepared by the electrical machinery committee.

Progress report No. 7 of the joint committee on welded rail joints, submitted by D. D. Ewing, A. I. E. E. representative on the committee, was received and ordered filed in the Engineering Societies Library.

The board voted to hold its next meeting in Kansas City, Mo., during the District meeting to be held in that city, October 22-24.

Other matters were discussed, reference to which may be found in this and future issues of ELECTRICAL ENGINEERING.

At Asheville - - - in 1905

IN this group in attendance at the Institute's 22nd annual convention held at Asheville, N. C., June 19-23, 1905, were five some-time presidents of the Institute: T. Commerford Martin, 1887-8; Charles P. Steinmetz, 1901-2; John W. Lieb, 1904-5; Samuel Sheldon, 1906-7; and C. O. Mailloux, 1913-14. Of all these, Doctor Mailloux is the only one now living.

Faraday Centennial to be Held in London

TO COMMEMORATE the one hundredth anniversary of the discovery of electromagnetic induction in 1831 by Michael Faraday, who, blacksmith's son though he was, has come to be known as the "creator of the age of electrical power," the Royal Institution and the Institution of Electrical Engineers of London, in cooperation with other British scientific societies, are arranging a centenary celebration to be held September 21-23, 1931. Government and university bodies as well as other scientific interests also have joined hands in offering their cooperation and assistance to make the celebration worthy of the occasion.

The following tentative program has been announced by the institutions sponsoring the celebration:

Monday, September 21

Afternoon

Reception of delegates from representative institutions throughout the world in the lecture theater of the Royal Institution.

Evening

Faraday commemorative meeting at Queen's Hall during which addresses will be given on Faraday's work.

Tuesday, September 22

Morning

Summer meeting of the Institution of Electrical Engineers begins with joint conference of the Institution and allied associations.

Afternoon

Visits and social functions.

Evening

Royal Institution: Conversazione at the House of Institution.

Institution of Electrical Engineers: Conversazione and Faraday exhibition at the Albert Hall.

Wednesday, September 23

Morning

Opening of the Faraday exhibition to the public. I. E. E. summer meeting and conference continued.

Evening

Opening meeting of the British Assosociation at the Central Hall, Westminster.

Honoring Faraday and his work, the program on Monday evening will include tributes by the British Prime Minister, the Rt. Hon. J. Ramsay MacDonald, the Duc de Broglie, Senator Marconi, Prof. Elihu Thomson, Prof. P. Zeeman, and other distinguished representatives of leading institutions throughout the world. The most outstanding feature of Monday night's program, however, will be the commemoration address by Sir William Bragg, who is one of Faraday's successors as head of the Royal Institution in London where the majority of the great scientist's experiments were carried out.

The entire commemorative meeting of Monday evening will be broadcast in England by the British Broadcasting Corp., while in the United States the National Broadcasting Company will rebroadcast a portion of the program between 4:00 and 5:00 p. m. eastern daylight saving time.

The exhibition to be opened on Wednesday has been arranged principally by the Institution of Electrical Engineers, and will be open to the public for a period of about ten days. The central feature of this exhibition will be reproductions and illustrations of Faraday's actual experiments, prepared by the Royal Institution, together with a display of some of his historic apparatus. Faraday's chemical and electrochemical work, which while not so well known as his discovery of electromagnetic induction nevertheless is hardly less remarkable, will be illustrated by means of special exhibits arranged by other cooperating societies.

Upon invitation of both the Royal Institution and the Institution of Electrical Engineers, the A. I. E. E. has appointed Dr. Wm. McClellan (F'12 and past-president) as its delegate to the celebration, and Dr. A. E. Kennelly (F'13 and past-president) as alternate.

Preceding the Wednesday morning opening of the Faraday exhibition, General Smuts, recently elected head of the British Association for the Advancement of Science, will deliver an address. On behalf of the other American societies who were invited to participate, Dr. F. B. Jewett (F'12 and past-president) then is scheduled to deliver brief felicitations by radiotelephone.

FARADAY'S DIARY TO BE PUBLISHED

Among the other many interesting features of the celebration comes the announcement of the publication of Faraday's diary, two volumes or more of which are expected to be ready by the time the celebration takes place. Faraday maintained a careful diary of all of his experimental work and this has been bequeathed to the Royal Institution and for over 60 years has been that organization's treasured possession. Although Faraday made extensive use of his notes in the preparation of his published works, the diary itself never has been published. As a permanent memento of the centenary celebration as well as of the man himself, managers of the Royal Institution have resolved to publish it in full.

Valuable Trophies Won in Summer Convention Sports

HEADLINER among the attractive sporting events offered at Asheville in connection with the annual summer convention of the Institute, June 22-26, 1931, was the annual tournament for the Mershon cup. Of chief interest in this connection is the fact that L. F. Deming (A'17) district engineer of the General Electric Company at Philadelphia, Pa., came into permanent possession of the Mershon trophy by virtue of his second winning of it. Mr. Deming won the first right to have his name engraved on the cup at the annual tournament held in connection with the summer convention at Cleveland, Ohio, in 1916. A beautiful silver tray also was presented to Mr. Deming as 1931 tournament winner by the Asheville convention sports committee. As runner-up in the Mershon tournament, R. O. Bentley (M'14) superintendent of the Public Service Electric & Gas Company, Newark, N. J., was presented with a beautiful silver bowl.

A silver bowl also was presented to S. K. Bushnell (A'22) Philadelphia sales manager for the Aluminum Company of America, for achieving low gross of 77 (par 71) in the qualifying round. A. H. Sweetnam (M'18) superintendent of the electrical engineering department of the Edison Electric Illuminating Company, Boston, also won a silver bowl for his low net of 60 (80-20) in the qualifying round.

In connection with the second round of the Mershon Cup event, a silver bowl was won by E. W. Dillard (A'16-M'30) electrical engineer for the New England Power Association, Boston, for his happy choice of 76 as a kicker's handicap (100-24). Tied with Mr. Dillard so far as net scores in this event were concerned, were R. A. Monroe (A'30) hydraulic engineer for the Aluminum Company of America, Pittsburgh, and G. A. Kositzky (M'22-F'29) chief engineer of the Ohio Bell Telephone Company, Cleveland. The prize was awarded by lot to Mr. Dillard.

For medal play handicap, two silver bowls were awarded, one to H. C. Don Carlos (F'18) chief operating engineer for the Hydro-Electric Power Commission of Ontario, Toronto, for his low gross of 82; and one to R. A. Monroe for his low net of 69 (84-15).

In the ladies' putting contest held on the 18-hole lawn course of the Grove Park Inn at Asheville, Mrs. W. K. Vanderpoel of South Orange, N. J., won first place and received a pair of silver bowls. As runner-up, Mrs. A. E. Bettis of Kansas City, Mo., won a silver plate.

In men's singles at tennis, J. K. Peck (A'27) assistant engineer for the National Electric Light Association, New York, came out best man receiving a silver bowl as his prize. As runner-up, E. F. Lopez (A'16-M'18) manager of the National Import Company, Mexico City, won a set of six silver ash trays.

Winners of Mershon Trophy

A. M. Schoen	1912
J. C. Mock	1914
E. W. Allen	1915
L. F. Deming*	1916
A. A. Brown	1919
M. G. Kennedy	1920
Howard Maxwell	1921
Philip H. Chase	1922
G. L. Knight	1923
R. O. Bentley	1924
C. E. Stephens	1925
H. C. Don Carlos	1926
A. H. Sweetnam	1927
W. C. Heston	1928
W. S. Lee	1929
Wills Maclachlan	1930
L. F. Deming*	1931

*Permanent possession gained by virtue of second winning.

Illumination Engineers Meet in October

The twenty-fifth annual convention of the Illuminating Engineering Society will be held at the William Penn Hotel, Pittsburgh, Oct. 12-16. Indications are that this convention will attract wide attention, several unusual additions having been made to the technical program, according to official announcement. There will be also a special program commemorating the society's silver anniversary.

Recognizing the present day importance of safety in night flying, the society has given over an entire session to the discussion of aviation lighting. Central-station lighting also will be given an important place on the program.

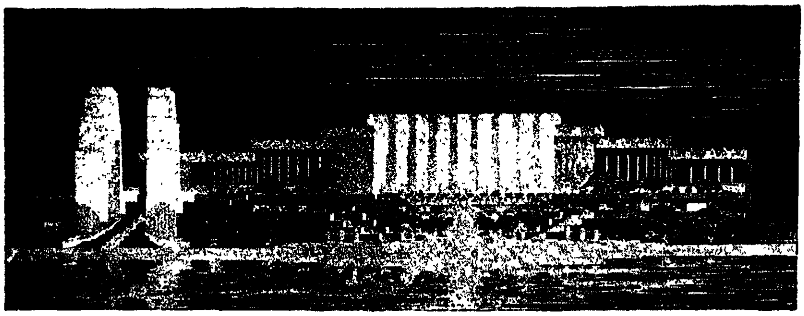
A. W. Robertson (A'27) chairman of the board of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, is chairman of the general convention committee, and J. A. Hoeveler of the Pittsburgh Reflector Company is chairman of the convention executive committee; P. H. Powers (M'30) vice-president of the West Penn Power Company and Joseph McKinley, vice-president of the Duquesne Light Company are serving as vice-chairmen. The committees in charge invite early registration by all who expect to attend.

Polish Engineering Secretary Visits U. S.

Joseph Podoski, secretary-general of the Polish Association of Electrical Engineers, spent the first two weeks of August touring the eastern portion of the United States in the interests of his organization. Mr. Podoski spent appreciable time acquainting himself with the policies and operating procedure of the American Institute of Electrical Engineers and the American Standards Association; he was interested also in electric power problems and railway electrification, spending several days visiting manufacturing plants and operating properties in an effort to gain a first-hand impression of American technique.

Mr. Podoski is one of the first Polish engineers to visit the United States under the reciprocal visiting membership privileges provided by action of the board of directors several years ago and recently extended to include the Polish Association of Electrical Engineers. Under this arrangement Institute headquarters in New York receives and forwards mail, upon presentation of proper credentials provides letters of

"A Century of Progress" Electrical Group



GROUND was broken Monday, July 20, 1931, for the Electrical Group, fifth building of Chicago's 1933 World Fair. The building was designed by Raymond Hood of New York, is 1,200 by 300 ft. in plan, two stories high, and of striking modernistic design employing a combination steel and special wallboard exterior; white, yellow, red, black, and blue are to be dominant colors. This structure will be embellished with hanging gardens and paved terraces, and will provide generous areas for the exhibition of generation, distribution, utilization, and communication equipment.

---

introduction, affords a convenient meeting place for appointments, and places at the disposal of foreign engineers the resources of the Engineering Societies Library. Normally, these privileges are available for a period of three months, but are subject to extension for cause. Under the recently established arrangement members of the A. I. E. E. visiting Poland will receive full privileges from the Polish organization providing formal application is made through Institute headquarters in New York.

A. C. Langmuir Prize in Chemical Research Awarded

Dr. Linus Pauling, who at thirty has published nearly fifty papers in the field of pure science, and has won a full professorship in the California Institute of Technology, has been chosen as the first winner of the A. C. Langmuir prize of the American Chemical Society. The work of Pauling who will receive the award at the eighty-second meeting of the Society at Buffalo, September 2, has had to do with crystal structure, the quantum theory of the dielectric constant of gases, atomic and molecular structure, and determination of the nature of chemical bonds.

The Langmuir Prize, awarded for the first time this year, is bestowed "in recognition of the accomplishment, in America, of outstanding chemical research by a young man or woman preferably working in a college or university." It emphasizes, according to the announcement, the debt industry owes to pure science. "Outstanding chemical research for the purposes of the award," it stipulates, "is that which is of unusual merit for an individual on the threshold of his career in chemistry."

Dr. A. C. Langmuir, brother of Dr. Irving Langmuir, noted scientist of the General Electric Company, is an industrial chemist, teacher, and author, whose principal researches have dealt with shellac and glycerine. He first became interested in chemistry while a student at Irving Institute, Tarrytown-on-Hudson, setting up a small laboratory in his home. His experiments attracted the curiosity of his younger brother, who, with this as a starting point, has won worldwide fame in electrical research.

Secret Ray Light Applies Train Brakes.—An automatic stop system for trains, invented by Major Raymond Phillips of England, enables a person on the ground to apply the brakes and stop the train. All the person on the ground needs is a hand lamp that works a secret ray. When this light is thrown on an oncoming engine the ray works a special form of light-cell switch which applies the engine's vacuum brakes.—*Telegraph & Telephone Age, July 16, 1931.*

Photoelectric Cell Controls Street Lights

In Albany, N. Y., nine street lighting circuits are turned on automatically as soon as a certain predetermined degree of darkness occurs, regardless of the hour of the day. The photoelectric device which provides this automatic control is mounted on the roof of the Albany service building of the New York Power and Light Corporation, and is one of the first such control units to be placed in commercial service. As long as the predetermined degree of darkness prevails the device keeps the street lights in service, cutting them off upon the advent of sufficient daylight.

According to the General Electric Company "ultimately all the street-lighting circuits in the city will be operated by similar equipment . . . "

It is claimed that the photoelectric-tube device is more flexible and positive in operation than are time switches or manual operation. For example, during the 97 per cent total eclipse of the sun expected in 1932 Albany street lights probably may be expected to turn on automatically, as they also may upon very dark and stormy days. Further, seasonal changes will be taken care of automatically.

Arthur Wright, noted English consulting engineer and a pioneer in meter engineering, died in England, July 28, 1931, at the age of 73. A native of London, the first plan for him was to enter the medical profession; but he deviated from this course to take up electrical engineering, and as the first electrical engineer for the Brighton Town Council, installed the Portslade generating station. He was well-known in this country, visiting twice each year to instruct the employes of the Edison Electric Illuminating Company, Boston, in the latest developments of European engineering. As representative of the United States National Committee of the International Electrotechnical Commission, he attended the London meeting (1929) and the Stockholm meeting (1930) of Advisory Committee No. 2. Until six months ago, when his health failed, he was a member of the Institute which he joined in 1906 as an Associate.

Homer Eldredge Niesz, manager of industrial relations and vice-president of the Commonwealth Edison Company, Chicago, president of the National Safety Council and a member of its executive committee, died August 7, 1931, of peritonitis. He was 63 yr. of age.

Airplanes Carry South American Freight

A fleet of three G-31 Junkers planes of the Guinea Airways is reported as having been chartered primarily by the Bulolo Gold Dredging, Ltd., for hauling heavy mining equipment and supplies from the coast to their relatively inaccessible gold mines, and to carry back for export the precious metal itself. Each plane uses three 450-hp. air-cooled Bristol-Jupiter engines, giving a full-load speed of 115 mi. per hr. On a trial flight one of these planes carrying a 3.5-ton load of freight plus a crew of three and fuel sufficient for flight of 1½ hr., climbed 7,500 ft. in 11 min. With one side engine cut out, the loaded freighter in 2 min. gained nearly 500 ft. of elevation.

Bucket dredges equipped with eighteen Westinghouse motors ranging in size up to 200 hp. each, switching equipment, and 200-kw. transformers are typical of equipment that has been flown the 32 mi. inland to the British New Guinea gold fields. Much shorter than the former circuitous water route, the air line hurdles mountains more than 2 mi. high.

American Engineering Council

Oil Pollution of Water Reported on Decline

Pollution by oil of coastal and inland waters in the United States is declining, it is indicated in a recent report of the American Engineering Council's joint committee on oil pollution.

Legislation to extend federal jurisdiction over waters which are under state control is opposed by the committee, of which Robert S. Weston of Boston, representing the American Society of Civil Engineers, is chairman.

"In reviewing the general problem of pollution by oil," the report declares, "the committee quite frequently has been confronted with the fact that one of the principal offenders in this connection is the United States Navy, which it is reported discharges oil from oil-burning warships without much regard for state or federal rules."

Replies to a questionnaire sent to sanitary engineers in 44 states show that pollution is believed to be decreasing in 25 states, and increasing in eleven. In six states the question was regarded with doubt. Of greater importance to the committee, however, is the fact that in 26 states the present state machinery was thought to be adequate to control the situation. In only twelve states was it felt that this machinery was inadequate.

House and Senate bills to enlarge federal authority are characterized by the committee as "most undesirable." These measures make it unlawful for any person to discharge oil by any means into or upon navigable waters, or upon any of the Great Lakes, their harbors or their connecting channels. Penalties are provided for violation of the law, the administration of which would be placed in the War Department.

Other members of the American Engineering Council's oil pollution committee, which was organized by G. T. Seabury of New York, secretary of the American Society of Civil Engineers, are: Abel Wolman, Baltimore, chief engineer of the Maryland State Department of Health, representing the American Society of Civil Engineers, secretary; W. H. Gartley, vice-president of the Philadelphia Gas Works Company, and W. C. Morris, New York, vice-president of the Consolidated Gas Company, the American Society of Mechanical Engineers; C. V. Weston, consulting engineer of the Chicago Surface Lines, and J. William Wetter, manager of Madeira Hill and Company, Philipsburg, Pa., the American Institute of Mining and Metallurgical Engineers; Dr. H. C. Parmelee, New York, editor of *Engineering News-Record*, and A. E. Marshall, Corning (N. Y.) Glass Company, American Institute of Chemical Engineers.

Personal

H. L. Doherty (F'13) according to recent disclosure through the columns of the society weekly, *Cleveland Town Tidings* (July 18, 1931) was the one who made financially possible the first floodlighting of the Statue of Liberty. George Williams, well remembered figure at Nela Park, conceived the plan and proposed it to the New York *World* which promptly approached Mr. Doherty, then associated with Mr. Williams, to underwrite the undertaking and promise to make good any deficit which might exist after all contributions were in. The *World* itself headed the list with $1,000 and 80,000 persons subscribed to the cause; not, however, until Mr. Doherty's promise of financial support had been obtained. The amount for which he ultimately gave his own check amounted to several thousand dollars. His part in the plan was pledged to obscurity, and neither his nor Mr. Williams's names were to appear in any publicity of the scheme. Since 1916 the true facts have remained a secret. Mr. Doherty's advance in the world of finances presents an interesting history. A news boy in the city of Columbus, Ohio, at the age of ten, he deserted that source of revenue two years later to become an office boy. By the time he was twenty he was manager of a public utility, and at thirty-five was a recognized leader in utility engineering and finance.

C. L. Dawes (M'15) has been advanced from the rank of assistant professor of electrical engineering to associate professor at Harvard University. Mr. Dawes has done much valuable research work in the insulation field, contributing considerable to technical literature in series of articles "Ionization Studies in Paper-Insulated Cables" and others. He has held office on the N. E. L. A. cable research committee and the A. I. E. E. committee on dielectrics and subcommittee on definitions and terminology; is student counsellor and was a member of the A. I. E. E. committee on student Branches. He is a member of the National Research Council.

T. R. Langan (M'30) who has been assistant manager of the northeastern district of the Westinghouse Electric & Manufacturing Company, now has been appointed manager, with headquarters in New York City. Before going to New York, Mr. Langan served his company in Philadelphia, Baltimore, Buffalo and as manager of the Syracuse office. He has been active also on engineering committees of the A. E. R. A., was president of its Metropolitan Section in 1928 and for the past three years has been busy as a member of the subject committee of the New York Railroad Club.

W. F. James (M'20) formerly the Middle Atlantic district manager of the Westinghouse Electric & Manufacturing Company, has been appointed assistant to the commercial vice-president of the Atlantic Division of that company. He has been a member of the Westinghouse organization since 1909. Mr. James is a past-president of the Electrical Association of Philadelphia and of the Engineers Club of Philadelphia, a member of the industrial relations committee of the Philadelphia Chamber of Commerce, and a member and past regional vice-president of the A. I. E. E.

R. J. Wensley (A'28) creator of the televox, first of popular mechanical robots, has been transferred from the East Pittsburgh engineering department of the Westinghouse Electric & Manufacturing Company to the company's meter department at its Newark works. Mr. Wensley has done notable work in connection with switchboard and automatic switch design and is a recognized authority in the field of intricate electrical control equipment. During 1929 he served on the A. I. E. E. subcommittee on automatic substations.

G. I. Wright (M'28) in charge of electrification for the Reading Company (Philadelphia) since 1927, on May 16, 1931 was made its chief electrical engineer in charge of all electrical and signal engineering. Mr. Wright, who at one time was assistant electrical engineer of the Illinois Central Railroad Company, continues as a member of the A. I. E. E. transportation committee. His new appointment is largely in recognition of the capacity he has shown in the work.

D. C. Jackson, professor of electrical engineering at Massachusetts Institute of Technology recently received the annual Lamme Medal award of the Society for the Promotion of Engineering Education, presentation being made at the annual convention at Purdue University, Lafayette, June 17, 1931. This award is made "for accomplishment in technical teaching or actual advancement of the art of technical training."

H. E. M. Kensit (M'08) after nearly twenty years in the Dominion Civil Service, retired August 1, 1931, to engage in private practise. His investigations and construction work in the United States and Canada included a detailed investigation of The South Saskatchewan Water Supply Division Project, involving comparative costs from all available power sources; water, steam, gas, and oil.

E. W. Loomis (A'19) who a few years ago was advanced from manager of the mill and mining section of Westinghouse Elec. & Mfg. Company to manager of the company's northeastern industrial division, now has become Middle Atlantic district manager with headquarters in Philadelphia, Pa.

T. C. McFarland (A'22) who for the past year has been doing special work in engineering at the Bell Telephone Laboratories, Inc., New York, now has returned to Berkeley, Calif., to resume his duties as associate professor of electrical engineering at the University of California.

R. G. Meyerand (A'28) who has been serving the Stone & Webster Engineering Company (Boston) as assistant to the chief electrical engineer, has been appointed sales engineer of the Rockbestos Products Corporation, New Haven, for its New England territory.

W. S. Richhart (M'13) manager of the light and power department of the Indiana Service Corporation, Fort Wayne, Ind., one of the Insull properties, now has assumed charge of the distribution service of all Insull properties included in the Midland United Company.

W. M. Herbruck (A'25) formerly with the engineering department of the Ohio Power Company, Canton, Ohio, now has the position of chief electrical inspector for the American Electric Switch Corporation, Minerva, Ohio, still retaining residence in Canton.

K. B. Thornton (M'13) who for a number of years, has been serving the Canadian Electric Railway Association at a recent meeting in Ottawa was elected president, the highest honor that can be conferred upon an electric railway operator in Canada.

W. S. Gifford (A'16) president of the American Telephone & Telegraph Company, New York, N. Y., was elected a member of the American Philosophical Society at its recent annual meeting held at the University of Pennsylvania, Philadelphia, Pa.

A. B. Day (M'16) president and general manager of the Los Angeles Gas & Electric Corporation recently was elected president (1931-1932) of the Pacific Coast Electrical Association, in which he has been actively interested for several years.

O. K. Marti (M'27) formerly chief engineer of the American Brown Boveri Co., Inc., Camden, N. J., is now associated with the Allis-Chalmers Mfg. Company in Milwaukee, Wis., as engineer in charge of rectifiers and railway equipment.

L. B. Andrus (F'19) president of the Indiana Electric Corporation, and a Life Member of the Institute, has been chosen by the National Electric Light Association to assume the presidency of its Great Lakes Division for 1931-1932.

W. E. Gutzwiller (A'30) until recently electrical engineer for the American Brown Boveri Co., Inc., Camden, N. J., has moved to Milwaukee, Wis., to take a position in the rectifier department of the Allis-Chalmers Mfg. Company.

A. S. Brown (A'30) instructor in the electrical engineering department of the University of Kansas, Fayetteville, Ark., until September 1 then became graduate research assistant, Kansas A. & M. College, Manhattan, Kansas.

E. H. Morris (A'23) for many years chief engineer of the Board of Railroad Commissioners, State of North Dakota, recently was appointed chief engineer of the Public Service Commission of West Virginia, Charleston.

G. T. Harness, Jr. (A'30) will serve in the capacity of assistant in E. E. at California Institute of Technology, Pasadena, on leave of absence from the College of the Pacific to work for his Ph. D. degree.

T. A. Fawell (M'20) formerly connected with the San Francisco office of the Marwood Company of California, Ltd., has been appointed manager of the Los Angeles office of that company.

R. C. Marshall, Jr. (M'19) who has been serving the Sumner Sollitt Co., Chicago, Ill., as president, is now vice-president in charge of the B-W Construction Company, also of Chicago.

R. D. Bean (A'21) who was manager of engineering development for the Brown Instrument Company, Philadelphia, is now chief engineer of that company.

President C. E. Skinner is the appointed representative of the American Standards Association on the council of the International Standards Association.

Obituary

William E. Richards (A'14-F'26) superintendent of electrical distribution for The Toledo Edison Company, Toledo, Ohio, died suddenly in his office August 12, 1931. He was born at Waynesburg, Ohio, October 20, 1863. In the early eighties he installed and operated an electric light plant for the Thompson-Houston Company at Newton, Iowa, and in 1891 returned to Ohio in responsible charge of electrical and mechanical operations for the Consolidated Street Railway Company, the various organizations of which occupied him until his death. Many of the advances of the Toledo Edison system were pioneered by him; he also planned and installed the floodlighting system in the Statue of Liberty, receiving therefore a gold medal from the City of New York.

Besides his membership in the Institute, Mr. Richards was a member and an active worker in the Toledo Chamber of Commerce, The Edison Association, the National Electric Light Association, the Illuminating Engineering Society, the Ohio Good Roads Federation, and several other local organizations, professional and social. He was at one time chairman of the Institute's Toledo Section. Endorsing his transfer to the grade of Fellow of the Institute, J. B. Taylor (F'14) consulting engineer, General Electric Company, stated in 1925 that "Mr. Richards has met and solved many special problems in the distribution of power, both d-c. and a-c., at low and high voltage. Resourcefulness and ingenuity exercised over a long term of years gives him a unique position in the central station field."

Alva C. Dinkey (A'97) former president of the Midvale and Carnegie steel companies, and a pioneer in the steel industry in Pennsylvania, died at his home August 10, 1931, after a three-months' illness. He was sixty-five years old, and a well-known figure in the great steel activities of the country, having been engaged in the steel industry since beginning work in the Edgar Thomson Steel Works at the age of thirteen. He became president of the Midvale Steel and Ordnance Company, later the Midvale Steel Company, in 1915. His interest was largely in the electrical end of the steel industry, and throughout his life he was a close friend of Charles M. Schwab. Mr. Dinkey was a member of The American Society of Mechanical Engineers, the Society of Naval Architects and Marine Engineers, the Engineering Society of Western Pennsylvania, the Engineers Club of Philadelphia, the American Association for the Advancement of Science, and the Academy of Natural Sciences. He also held membership in the Racquet, Manufacturers, Sunnybrook, Five O'Clock (Philadelphia) Duquesne (Pittsburgh) clubs and the Indian House and Pennsylvania Society of New York.

George Gault Cree (A'22-M'30) of the central station engineering department General Electric Company, Schenectady, was drowned in Lake Ontario July 20, 1931. He was attending camp and had gone for a sail with a number of the company's officials, when a violent squall capsized the boat. Mr. Cree, who was not a strong swimmer, sank and exhaustive effort failed to reach him. Born in Scotland in 1888, he was educated in English and Scotch schools, and entered the General Electric Test course at Schenectady in 1919. After a number of years abroad he entered the central station engineering department where his experience and personality won the confidence of the utilities with which his work brought him in contact. He was a member of the N. E. L. A. apparatus committee, and of late had become prominent in local Boy Scout movements.

Bruce Ford (A'11) until recently general manager of the Electric Storage Battery Company, Philadelphia, of which he also was vice-president, died at his home near Philadelphia, August 10, 1931, after a brief illness. He was born in Brooklyn, N. Y. in 1873, and had been in the organization of the Electric Storage Battery Company since 1890, except for a few years in the early part of his career. More than fifty patents on inventions relating to storage batteries are registered in his name. Mr. Ford was a director of the Chloride Electrical Storage Company, Ltd., Manchester, England, and a member of the American Society of Mechanical Engineers, Franklin Institute, the Engineers Club (New York and Philadelphia), the Philadelphia Cricket Club, the Old Colony Club, and the Military Order of the Loyal Legion.

Lewis Judson Wells (A'24) sales engineer for the Diamond Electrical Manufacturing Company, Los Angeles, Calif., was killed in an airplane accident July 16, 1931. He had been with this company and its affiliated organizations since graduating from the California Institute of Technology in 1922. An interest in the art of flying led him to spend most of his leisure hours in the air.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Bunce, Lewis I., Rocky Hill, Conn.

Clark, Bernard, 79 Jenness St., East Springfield, Mass.

Cole, Will G., Box 222, Westwood, Calif.

Corriveax, F. M., General Electric Co., Schenectady, N. Y.

Deacon, L. O., 6 Ailsa Ave., East Malvern, Melbourne, Australia.

Furui, Shungo, Shibaura Engineering Works, Tokyo, Japan.

McLean, James S., 190 Old Army Road, Scarsdale, N. Y.

Melson, Sydney W., Yeatton Woolwich Road, Abbey Wood, London S. E. 2, England.

Mountain, C. E., Burma Elec. Supply Co., Mandalay, Burma, India.

Nuber, Frank J., 3831 Rokeby St., Chicago, Ill.

O'Shea, V., Jr., 115 Broadway, New York, N. Y.

Pistorius, L. H., 193 Jeppe St., Johannesburg, South Africa.

Prudham, W. M., 100 Biddle St., Wilkinsburg, Pa.

Schrock, John E., 3720 Main St., Lawrence Park, Erie, Pa.

Sullivan, John E., 6320 Kenmore Ave., Chicago, Ill.

Tate, William, Apartado No. 41, Puebla, Mexico.

Tung, C. T., c/o Stone & Webster Engg. Corp., Hopewell, Va.

Letters to the Editor

Has Man Benefited by Engineering Progress?

Apparently the first article of The Engineering Foundation's symposium, concerning the possible benefits accruing to and through mankind as a result of engineering progress, as published in the August issue of ELECTRICAL ENGINEERING (C. E. K. Mees, p. 642) has appealed to different people in different ways. Among the letters received by the editors are the following:

To the Editor:

Doctor Mees's article, "Has Man Benefited By Engineering Progress?" in the August issue, is a refreshing contrast to the average engineer's blind worship of mechanical progress. It is as pleasant as it is unusual to find an eminent technician free from the common error of identifying industrial with human progress.

If in accordance with Doctor Mees's definition, engineering is taken as embracing all of applied science, its development, particularly in the field of medicine, has certainly been of notable benefit to mankind. The gain is small, however, in comparison with the benefits which would result if progress in the subjective elements of civilization kept pace with technological advancement. That it has not done so is of course a truism. Moreover, the inability of men to cast off superstition in their emotional and social life as fast as they discard it in dealing with the mechanics of existence is fraught with the gravest menace. Machinery merely amplifies the capacity for evil of the stupid and sadistic herd and its leaders. "Against stupidity," said Schiller, "the gods themselves fight in vain." Give to stupidity or ferocity modern machine guns and automobiles, and the gods might as well retire from the conflict altogether. It looks at times as if they have already done so.

For all this the engineers are as much to blame as educators, priests and magistrates. The very success of the engineering profession places on it some measure of responsibility for the misuse of its implements. The engineer is both too proud and too humble. He is too proud, because, unlike Doctor Mees, he seldom apprehends the narrowness of his contribution. Because of the feeling of power he derives from it personally, he comes to regard it as an end in itself. He is too humble, because he will not even raise his voice in protest against the perversion of his creations. He is like a designer of firearms who having created a particularly neat and powerful engine of destruction, puts it into the hands of a chimpanzee and goes on his way rejoicing.

The stability of society is at least as important as the stability of an electrical distribution system; but as long as this attitude is general, there is no hope of curing the fundamental evils of communal life. On the contrary, blind industrial proliferation will merely increase our hazards and the extent of our failure. Both the lowly and those high in power are uneasily conscious of the inability of mankind to adapt itself to the complications of the Machine Age. The principal burden of shame is on the successful and the competent. It matters little to the individual whether he starves because there is not enough food in the world, or too much. But the latter condition is much more disgraceful to society than the former.

There is perhaps nothing that the engineer, as a highly specialized helot of business, can do in an immediately practical sense, but it is encouraging to see him begin to think along the lines of the forthcoming series of papers. He may learn that the proper study of mankind is man, and not merely transmission lines, circuit breakers, and car couplings. He may be forced to acknowledge that, at the present stage, psychiatry and the social sciences are more important than further progress in engineering, and if he is somewhat humbled in his own estimate of himself, it may increase his usefulness in the long run.

Sincerely yours,
CARL DREHER (A'23)
(Director, Sound Dept., R. K. O
Studios Inc., Los Angeles)

To the Editor:

You have asked for comments on the article, "Has Man Benefited By Engineering Progress?" by Dr. C. E. Kennedy Mees. It would require a rather extended discussion to refute Doctor Mees's beliefs. It is undoubtedly true that one's judgment on the influence of engineering progress on human welfare will depend upon the definition or assumption of the meaning of the term benefited. It seems to me that Doctor Mees has given an exceptional narrow meaning to this term. I believe the term human welfare, as used in the preamble of the Constitution of the United States, comes nearer expressing living conditions that have been influenced by engineering progress.

If we consider the contributions of engineering progress toward the fulfillment of the aims specified in the preamble of the Constitution, there is no doubt in my mind but what engineering progress has done more to promote the general welfare and to secure the blessings of liberty to ourselves and our posterity than all the philosophies written since Aristotle.

Doctor Mees asks the question, "will any student of history agree that the inhabitants of an American city are any happier on the whole than those of the Greek or Babylonian cities of the past?" The degree of happiness is incommensurable. If we substitute for happiness, welfare, I have no hesitancy in stating emphatically that the inhabitants of an American city have on the whole a much higher state of well being than the majority of the inhabitants of the Greek or Babylonian cities. It is useless to deny that the Greeks developed a high state of culture, but that culture was merely a crust superposed upon a state of society which today would not be tolerated even in a semi-civilized community. In so far as advancing the civilization—that is, improving the social conditions of the masses—of its own period is concerned, the philosophies of Greece and Rome did no more than the pyramids of Egypt or the palaces of Peru. Human progress was not arrested because ancient civilizations fell, but the civilizations fell because human progress had been arrested.

Doctor Mees still has the privilege of walking a short distance. At the same time he can ride a long distance if occasion demands, and on the way he may acquire by such experience an appreciation of life in remote regions. All of life and culture is not confined to a garden. The emotions aroused by the majesties of the Grand Canyon and of the snow-capped mountains are just as cultural as those aroused by a poem, a book on philosophy, or a growing radish. They are, however, beyond the confines of a garden and beyond the limits of short walk. Likewise, Doctor Mees still has the privilege of attending to his business in a leisurely manner, to live in a small city, to cultivate a small garden, but I see that he lives in Rochester, New York. Assuredly, then, the attractions of a large city are more alluring and satisfying than living in a small city.

Very truly yours,
C. M. JANSKY (A'06)
(Professor of Electrical Engineering, University of Wisconsin, Madison)

To the Editor:

A few comments on the article, "Has Man Benefited By Engineering Progress?" by Doctor Mees.

Perhaps it would be well to think of the advancement of modern life as a series of tedious climbs from one level to another with resting places along the way.

It is apparent that mankind has been advancing rapidly and fighting feverishly to maintain a higher level of living for the past decade. Without the equipment of life sufficiently perfected to hold the level, so that the accomplishment has been made with a sacrifice of human happiness.

It is quite apparent that the equipment necessary to the security of such a level has been satisfactorially perfected at this time; and that the plane of life can now be maintained, through its application.

The necessities of life can be abundantly supplied with the available equipment and with a very effective decrease in man hours that will occur when economic conditions are fully understood.

There is little to fear in the form of revolution, though at this time, such a turn might seem inevitable.

This new level of life with its new standards of living was arrived at rapidly and we do not yet know how to curtail its productivity without injuring human happiness. Though we know man hours must be decreased materially.

The solution slowly evolves as Engineering applies the Science of Economics.

Yours very truly,
ORRIN S. VOGEL (A'29)
(Electrical Engineer, Georgia Power Company, Atlanta)

To the Editor:

Dr. Mees, in the August issue of ELECTRICAL ENGINEERING, takes a very pessimistic view of engineering's contribution to human progress, and I should like to present a point of view that will lend a little more rosy tint to the accomplishments of science and its handmaiden, engineering. We all realize that points of view are many and are usually taken by choice according to the temperament of the chooser. It must be confessed that between two views equally rational and consistent with the facts of history I should choose the more optimistic.

The yardstick by which I should measure the progress of the world is *consciousness*. Of course there are many definitions of the term and much will depend upon which definition is chosen. The sense in which I wish to use it, is the very broad one which includes both intellectual and emotional knowledge. For a further interpretation of this concept we might give as one reference the books of Prof. Warner Fite. To increase consciousness seems fully as fundamental an aim or purpose of mankind as any mentioned by Dr. Mees, even in its narrowest sense.

Life from the very beginning can be interpreted and explained in terms of such a measure very remarkably. The discoveries of speech and writing are the very foundations of the human race as we know it, and it is reasonable to suppose that progress in the future will be the result of other such remarkable discoveries. A return to the state of the contented cow can be justified on many grounds, but not on the ground of increasing consciousness. Is it not proper to value the forces that have made us and look for their continuance in estimating progress?

Let us for a moment attempt to evaluate science in terms of increasing consciousness. Many of the results of science sink away into nothingness; for example, those things which create mere comfort and draw people from, rather than to, an active life. The great achievements, not always without pain and discomfort to many, appear as those that have added to better communication, recording, and understanding. Photography, wireless telephony, talking pictures, better transportation, cheaper books and magazines, and, in the realm of pure science, the new understanding of the universe and of the need for higher dimensions. These are the things that are going to lead to a race as much higher than we, as we are higher than the cave man.

It is true that engineering has been concerned almost entirely with material things, and in so far as it is limited to them it is insufficient; however, no one but an engineer will say that engineering is the whole of life. Owing to the spread of an artificial scientific attitude, religious fervor and spiritual awakening may even have suffered temporary setbacks, but how much greater will they be when man turns the instruments he is as yet just beginning to discover in the direction of things immaterial; immaterial yes, but more lasting and more powerful in human good than anything now imagined.

Yours very sincerely,
W. C. JOHNSON, JR. (A'29)
(Electrical Engineer, Industrial Engineering Dept., General Electric Co., Schenectady, N. Y.)

Employment Notes

Of the Engineering Societies Employment Service

Men Available

ELECTRICAL ENGINEER, 1930 graduate, 25, single. Eight months' construction experience; one summer with public utility, one year G. E. Test including six months on vacuum tubes. Eastern location preferred. Interested in any position except sales. Available on short notice. C-9591.

ELECTRICAL ENGINEER, 36, married, 18 years' experience on power plants, transmission lines, substations, switchboards, telephones, mine electrical equipment, motors, lighting, marine electrical work, draftsman. Five years' electrical engineer wiring for power, light, telephones, signal systems, elevators for all types of buildings. Also expert plumber, heater and tinner. C-9348.

1931 ELECTRICAL ENGINEERING GRADUATE, age 25. B. S. E. E. in well-known engineering college. Desires work in any of th following or similar classes: industrial control, research, radio, test, design, development or maintenance. Worked through school by alternating years at school with years at work. Excellent references. Industrial experience. Honor student. C-9518.

MANAGER, SUPERINTENDENT, RESIDENT OR OPERATING AND MAINTENANCE ENGINEER, technical graduate, B. S. in E. E., 22 years' experience, engineering, construction, operation and maintenance of steam; hydro and Diesel power stations, transmission and distribution systems, as well as special process and heavy mechanical equipment and industrial plants. C-9597.

ERECTING ENGINEER, 46, of broad experience in power plant construction, maintenance, and operation. Exceptional ability in the erection and wiring of switchboards, power plant auxiliaries, oil circuit breakers, and high-voltage outdoor substations. Available immediately. C-8792.

ELECTRICAL ENGINEER, 32, married, 8 years in iron and steel works, oil fields, etc.; electrical installation and maintenance. Three years central and substation electrical plant installation. Five years electrical drafting of rolling mill, coal mines, and public utility electrical plant. Anywhere United States or abroad. C-625.

1931 ELECTRICAL GRADUATE, midwest university, 22, single. Tau Beta Pi student. Desires connection with manufacturing or public utility concern. Location preferred, Middle west. C-9398.

ELECTRICAL CONDENSER ENGINEER with thorough knowledge and extensive experience in the design and application of impregnated paper, mica, and air dielectric condensers. Would like to organize or reorganize condenser department for reliable manufacturing company. Will present convincing details on receipt of correspondence. C-7970.

ELECTRICAL ENGINEER, specializing for the past four years in research and development work on hot-cathode neon arc lamps a-c. and d-c., low-voltage neon sign tubes, photo cells, mercury-rare gas, ultra-violet tubes. Desires to connect with company developing rare-gas arcs for television projection. C-9598.

GENERAL ENGINEER, primarily electrical, 37, countrywide experience with largest engineering and construction corporations. Responsible charge utility and industrial design, application, study, report, appraisal, operation and superintendence of construction. Successful contacting clients and handling men. Experienced in mechanical and structural practises. Now employed. Interview at Boston or New York. C-9627.

GRADUATE ELECTRICAL ENGINEER for shop supervision, research or development. Six years' shop, assembly and test. Twelve years design high-voltage out-door equipment. Knows shop tools by actually serving in shop. Has inventive ability, pleasing personality, and knows men. Age 40, married, now in Middle-West. C-9641.

ELECTRICAL ENGINEER, 24, single. Degree B. S. in E. E., Marquette '31. Three and one-half years' cooperative work in large manufacturing plant. Four years' housewiring experience. Location, Middle West, preferably Milwaukee. C-9642.

ELECTRICAL ENGINEER (Cornell), well known in South Africa for many years, and having an established engineering business in Johannesburg, seeks agencies for American electrical apparatus and supplies suitable for mining and industrial uses. C-9657.

ELECTRICAL, RADIO ENGINEER, 31, graduate with B. S. E. E. University of California. Experience in electrical and mechanical design, test and operation of radio and high-frequency circuits, apparatus. Experience in design and development of heavy power automatic switchboards and gang switches. Excellent references. Location preferred, New York. Available at once. C-6734.

ELECTRICAL ENGINEER, graduate of Lehigh University, 1930, age 25, one year on general test crew of large Pennsylvania Utility company. Mechanical and electrical experience. Three months for telephone company as student engineer. Can come for interview promptly. All references desired. C-9659.

ELECTRICAL ENGINEER with years of sales experience in the Middle West desires connection with headquarters preferably in Cleveland. University graduate in E. E. knows selling and advertising of technical products thoroughly. Would be excellent representative for growing manufacturer or publisher. B-8614.

MANAGER, electric light properties, 39, Protestant, married, 15 years' experience, sales, public relations, line-building, operation, maintenance, costs, franchise work, meters, transformers, accounting, billing, collections. District manager for property having 75 employees; sold out own property in Minnesota. Desires similar or departmental position anywhere; preference Middle West. Available immediately. Salary secondary to opportunity. C-9670.

COMMUNICATION ENGINEER, 31, single. Experienced telephone, radio installation; design, development of testing equipment for telephone, radio, sound-picture circuits; design, use of semi-, full-automatic testing circuits to eliminate human element in testing; industrial applications of photoelectric cells, thermionic tubes. Best references as to professional ability, personal integrity. Location, immaterial. Available immediately. C-9376.

ELECTRICAL ENGINEER, graduate eastern university, 1930 member honorary society, Iota Alpha. Ten months' experience Westinghouse Test on distribution and instrument transformers commercial tests and phase-angle measurements. Also in testing department, large public utility for a summer on engineering tests. Desires position in engineering field with opportunity. Location, immaterial. C-9564.

CENTRAL-STATION DESIGN ENGINEER, 33, graduate M. I. T., eight years' experience covering complete engineering design of generating stations, high-voltage switching stations, substations and transmission lines; including estimates, specifications, and purchase of equipment. Experience includes 18 months on the G. E. Test course and one year in th field. Married. C-4338.

ELECTRICAL DESIGNING ENGINEER, 25 years' experience with public utilities and industrial companies, power house and substations, steam and hydroelectric, copper ore and nitrate ore reduction plants, married. Seeks permanent connection, responsible position, anywhere in United States and Canada. New York State P. E. license. B-7031.

ELECTRICAL ENGINEER, 28 married, 1924 graduate of recognized technical college with degree of E. E. Three years' experience with large metropolitan public utility in charge of relays and system protection. Three years' experience in electrical laboratory investigating and testing all types of electrical devices. Location preferred, New York City or vicinity. B-8793.

EXECUTIVE ENGINEER (M. I. T. electrical post graduate degree). Fifteen years' experience with metropolitan power companies, large electrical manufacturer and in aeronautic test, design, research and construction. Extensive knowledge. Good leader with initiative. Will travel. B-1041.

ERECTING ENGINEER, 46 broad experience in power-plant construction, maintenance and operation. Exceptional ability in the erection and wiring of switchboards, power plant auxiliaries, oil circuit breakers, and high-voltage outdoor substations. Availabl immediately. C-8792.

ENGINEER, age 27, B. S., three years and seven months C. E. experience. Desires position with hydroelectric project. Qualified for chief of party, transitman, estimator, assistant engineer. C-9382.

ELECTRICAL ENGINEER, over 17 years' experience in light and power field, several years in charge of work, desires position in charge of electrical engineering work for central station company, either with or without construction and operating duties. University graduate, good technical knowledge, and ability to handle men. B-1923.

1928 GRADUATE ELECTRICAL ENGINEER, age 24, General Electric Company over two years, including one year test on power and control apparatus and one year laboratory development and measurement. Desires position with industrial company or with scientific school. Prefers Philadelphia or New York. C-9683.

SENIOR ELECTRICAL ENGINEER, 35, married. Considerable experience in projection and complete design of mills, power plants, distribution and other industrial phases. Some development experience. Urgently in need of placement. B-3172.

RAILROAD ELECTRICAL ENGINEER, six years varied design, construction, operating experience large western and eastern railroad electrifications; familiar with American, European practise regarding transmission lines, substations, catenary systems, motive power. American, college graduate, good references. A. I. E. E., A. S. M. E., A. R. A., AEREA. membership. C-8463.

GRADUATE ELECTRICAL ENGINEER, B. S. in E. E., 1931. Single, 25. Courses taken include design, radio, and telephone.

Slight knowledge of Spanish and German. One year's experience with electrical prospecting company. Desires position with any manufacturing or engineering concern. Location and salary secondary, opportunity and experience being main factors. C-9692.

1931 GRADUATE ELECTRICAL ENGINEER, age 22, married. B. S. in E. E. from Pennsylvania State College. Three months' experience as assistant engineer with telephone company and two months in system operating department of large power company. Desires position with utility, engineering, or manufacturing concern. Location, immaterial. References. Available immediately. C-9695.

VALUATION ENGINEER, graduate of technical school of standing with B. S. E. E. degree, 29, married. Over five years' experience in appraisal and financial work for public utilities. Desires position with consulting engineer or with banking or investment company dealing in utility securities. Present unemployment due to a merger. Available immediately. C-9700.

ELECTRICAL ENGINEER, B. S. degree 1929, single, 23; desires engineering or sales work with opportunity for advancement. Has year and a half experience in service department of power company. Location, immaterial. References. Available immediately. C-9034.

ELEVATOR ENGINEER, 37, married, E. E. degrees at Cornell, '20. Six and one-half years' practical experience in the engineering, manufacture and production of elevators; three additional years in application of control and signal equipment to elevators. Desires sales or sales engineering work. Location, Midwest preferred. C-4486.

1931 TECHNICAL GRADUATE of eastern college, B. S. in E. E. Experience in Bell telephone laboratories, Western Electric Company and Perryman Vacuum Tube Company. Familiar with power-line carrier telephony, vitaphone presentation, vacuum-tube production and research. Honor student at college. Desires position with a well-organized firm. C-9661.

ENGINEER, for the past 20 years in responsible positions in connection with design and construction of electric power plants, switching stations and transmission lines; also reports on electric utilities, with antecedents as blast-furnace, rolling-mill and waterworks engineer, seeks responsible work requiring preferably a combination electrical, mechanical and structural engineer. C-9332.

ESTIMATING ENGINEERING, B. S. degree in E. E., age 34, married. Ten years' experience with large company manufacturing electrical power equipment, includes designing electrical and mechanical construction and calculating cost, weight, and dimensions of this apparatus in connection with customers' negotiations. Available at once. Location, immaterial. C-4633.

ELECTRICAL ENGINEER, B. S. degree Lehigh University, single, age 22. Desires position with utility, construction, or manufacturing company. Location, immaterial. One summer with New York Edison Company, Test Bureau. Available immediately. C-9702.

ELECTRICAL ENGINEER, B. S. in E. E., University of Michigan, August 1931. Eight months student engineer with electrical manufacturer prior to graduation. Associate member of Sigma Xi. Full member of Sigma Rho Tau honorary speech society. Unusual success in collegiate debating and public speaking indicate desirability of sales work. Location, immaterial. C-9709.

GRADUATE ELECTRICAL ENGINEER, B. S. in E. E., 1931, intends to study for M. S. degree at night; 21, single. Desires position in any electrical engineering field including radio or vacuum-tube work. Available at once. Location, New York preferred but not essential. C-9467.

ELECTRICAL ENGINEER, 26, single, Swiss graduate, 1928. Full quota immigrant. Experience: assistant designer of transformer stations and substations. Insulator testing. Research in the States. Graduate student at M. I. T. Speaks fluently French, English, and German. Connection with outstanding firm; testing, research, or manufacturing desired. Location, immaterial. C-9654.

GRADUATE ELECTRICAL ENGINEER, B. S. in E. E., 1928, 26, single. Two and one-half years' experience as designing engineer on distribution and metering transformers. Desires position with public utility, contracting, or industrial concern. Available at once. Location, immaterial. C-9693.

ELECTRICAL ENGINEER, two years' Westinghouse Test; 25 years' experience, partly in South America as engineer and manager of public utilities, and mining. Speak Spanish fluently. Also Diesel-engine and refrigeration experience. Location, immaterial. B-5912.

GRADUATE ELECTRICAL ENGINEER, age 28, married, with eight years' experience in industrial plant construction and maintenance; railway electrification; power-plant design, estimating, and construction. Supervisory experience on construction and costs with contractor. Desires position with utility manufacturer or contractor, where ability to handle labor and produce results is a prerequisite. C-4428.

1931 ELECTRICAL ENGINEERING GRADUATE, age 23, B. S. at North Carolina State College. Desires position with opportunity for advancement with utility, manufacturing, or any other engineering firm. Can furnish best of references. Location preferred, East or Middle West. C-9660.

ELECTRICAL ENGINEER, B. S. in E. E. '31, 23, single. Has had some experience in telephony. Desires position with power or telephone company. Available immediately. Location, immaterial. C-9710.

1931 TECHNICAL GRADUATE, B. Sc. in E. E. from a midwestern university, desires permanent connection with chance for advancement. Age 26. Location, immaterial. Available immediately. C-9717.

SALES ENGINEER, graduate E. E. and N. Y. State licensed professional engineer, twelve years' experience, capable correspondent, thoroughly familiar with routine office details, sales-promotion programs, training and handling men, direct sales to industrials and utilities, preparing specifications, designing industrial motor drives, control wiring diagrams and substation design. C-5239.

JUNIOR ENGINEER, 1931 graduate, B. S. E. E., University of Alabama. Desires position with utility, construction, manufacturing company. Location, immaterial. Experienced in power-plant and building installation and industrial control, having been employed for eight summer months and one full year, first as electrician helper and later as first-class electrician. C-9446.

GRADUATE ENGINEER, B. S. in E. E., 25 years' experience in electrical, mechanical design operation, maintenance and construction of power plants. Last seven years on construction and putting in operation of power-plant equipment. Combustion, heating and high-pressure piping installations. Available now. C-7848.

SALES ENGINEER AND EXECUTIVE, electrical and mechanical training, seven years' sales engineering and executive experience in application of precision equipment to electrical equipment. Would like opportunity to develop sales of mechanical product allied with electrical industry or of electrical nature sold to central stations and industrials. C-5431.

1930 ELECTRICAL ENGINEER, Rensselaer Polytechnic Institute, 24, 5'8¾", 160 lb., in very good health, desires immediate connection. Will go anywhere, anytime; will take foreign service if necessary. Hydroelectric and power maintenance, construction and installation before graduation. Willing to start in as draftsman if necessary. Quite studious and ambitious. C-7936.

ELECTRICAL ENGINEER, technical graduate, 32, married. Twelve years' experience in design of steam and hydroelectric power stations, bus-stations, and industrial plants, including estimates, costs, specifications, purchase of equipment, drafting, and construction supervision. Desires position with public utility, engineering or industrial concern. References. New England preferred but will consider other location. C-9715.

ELECTRICAL ENGINEER with wide practical experience in design, construction, operation, distribution, superintendence of gas and electric public utilities, desires permanent connection with industrial organization in the Middle or Far West. C-9668.

RECENT GRADUATE, 23, Pratt Institute in industrial electrical engineering. Desires position with power company or related work in manufacturing or construction. Location, East. C-9727.

MECHANICAL AND ELECTRICAL ENGINEER, research, development, reports. Phys. tests of material. Metallography, X-ray analysis. Languages: French, and German. Available on short notice. Location, immaterial. C-6994.

ELECTRICAL ENGINEER, graduate Lehigh University 1922. Experienced all kinds construction, transmission work power plants, substations, etc. mostly as draftsman laying out such work. Also familiar with electrification in anthracite fields. Willing to accept drafting, engineering, or any other electrical position. Location, eastern states preferable but anywhere considered. C-9723.

GRADUATE ELECTRICAL ENGINEER, 22, single, B. S. in E. E. 1931, Lehigh University. Three months' summer experience testing department large public utility. Desires position with utility company. C-9721.

INTERNATIONAL OR DOMESTIC BUSINESS, university graduate, 31, thoroughly trained and experienced, seven years engineering and business U. S. and abroad; export, power system planning, developments, reports, estimating, organizing; foreign languages: German, Spanish, some French. Desires connection holding company or trade; will consider representing concern abroad. Available short notice. C-3534.

INTERNATIONAL BUSINESS, electrical engineer, 30, single; citizen, college graduate here and abroad, widely traveled, speaks Scandinavian, German, fair French, some Russian, five years' American engineering experience, power plant and substation design and construction. Desires permanent position with holding company or representating manufacturer abroad. Excellent references. Personal interview desired. Location immaterial. C-9730.

ELECTRICAL ENGINEER, 43, married; twenty years' electrical, power, and industrial plants experience in construction, maintenance of distribution and transmission lines; desires position with public utility or industrial plant. Can qualify as electrical superintendent. Used to handling men. Available short notice. Canada preferred but would consider other location. C-9459.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
A. K. Krauser, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

ELECTRICAL - MECHANICAL ENGINEER, 24, single, graduate Cooper Union night school of engineering, 1931, degree B. S. in E. E. Eight years' industrial experience including machine shop, mechanical, electrical design work; some radio and patent work. Speak German fluently. Desires position, vicinity of New York City or suburbs. Available immediately. Excellent references. C-8357.

ELECTRICAL ENGINEER, B. S. in E. E. from well-known institution, 1931, single, 22, available immediately. Summer experience in generator design, sales, and shop work. Research experience in industrial power tubes. Excellent scholastic record. References furnished. Moral habits and good health. Location, immaterial. C-9699.

ELECTRICAL - MECHANICAL ENGINEER, 44, married, technical university graduate. Eighteen years' practical experience; design, test, operation of a-c. and d-c. motors, generators, contactors, relays, switches, controllers, electro-mechanical devices. Elevator and hoisting equipment, construction and installation. Technical management. Development and production work. Location, New York City vicinity or East. Available immediately. B-5240.

ELECTRICAL - MECHANICAL ENGINEER, married, graduate electrical engineer, New York and New Jersey professional licenses, 15 years' experience illumination, flood-lighting, wiring, service vaults, house switchboards, and underfloor duct for office buildings. Maintenance and plant engineering work in textile, zinc, steel, and small parts manufacturing plants. Specifications, purchasing and executive experience. B-5026.

ASSOCIATE ELECTRICAL ENGINEER, 37, married, twelve years with Westinghouse; apprentice course, sales and shop. One and one-half years Western Electrical Engineering department, writing inspection methods instructions. Knowledge of oscillograph testing and meters. C-8817.

MANAGER, EXECUTIVE ENGINEER, 41, superintendent, consultant, sales engineer, assistant to major executive. Electrical utility properties, management organizations, industrials, manufacturers. Broadly trained, twenty years diversified responsibilities, five connections. Demonstrated ability large projects. Sound economical design, construction, operation. Extensive changeover programs, networks, underground systems. Vitally energetic, American. Salary not immediate objective. C-3963.

ELECTRICAL ENGINEER, experienced also in metallurgy and electro chemistry, has been employed for more than six years in physical research laboratories, desires similar position. B-9034.

1931 GRADUATE ELECTRICAL ENGINEERING, B. S. in E. E. University of Delaware, single, age 21. Special courses taken in physics and radio. Desires position with any manufacturing or engineering firm. Location, immaterial, opportunity and experience being main factors. Available immediately. C-9666.

ELECTRICAL ENGINEERING ASSISTANT, 26, married, college graduate, four years' transmission and distribution experience with public utilities on design, estimates, survey, and evaluation. Desires connection with public utility engineering department. New York City preferred, but will consider any United States location. C-5511.

1930 GRADUATE OF ELECTRICAL ENGINEERING, under the cooperative plan at Georgia Tech. Worked alternate months with public utility company in Georgia in the following departments: car-barn, gas, engineering, hydro-generation, and statistics. Since graduation has worked six months with transmission line construction crew. Any location. C-9210.

Instructors

ELECTRICAL ENGINEER, 36, desires position as professor or instructor in E. E. at college, university or technical school. University graduate; two and one-half years' instructor; two years' machine design with Westinghouse; seven years' design of electric power stations; competent supervisor. Correspondence invited. C-9593.

INSTRUCTOR in design engineering. Ten years' practical experience on the design, construction, installation and calculations of overhead distribution lines and underground networks. Location preferred, Southwest. Available at once. C-4784.

ELECTRICAL ENGINEER, B. S. E. E. '29, M. S. E. E. '31, leading university, eighteen months General Electric Test, 23, single. Desires to teach in technical university. Prefers Midwest. C-9320.

GRADUATE ELECTRICAL ENGINEER, M. S. in E. E., 1931 from M. I. T. General Electric Test experience. Experience in the design of motors and generators. Available upon short notice. Location, immaterial. C-9559.

ELECTRICAL ENGINEER, B. S. E. E. degree from southern university, 1930, age 21, single. Desires position with manufacturing concern offering a future, or as instructor in electrical engineering. Location, immaterial. Available at once. C-9607.

ELECTRICAL ENGINEER, college graduate, advance studies, 29, married, Westinghouse training. Six years' experience as designer of electrical circuits and mechanical details of control apparatus. All kinds of control apparatus, specializing on elevators. Qualified for responsible position. Location, immaterial. Available on short notice. C-9638.

ELECTRICAL ENGINEER, teacher, married, university graduate. Four years instructor in state university; five years in testing and design departments of operating company; six years with consulting engineering firm in central station design; eight years with engineering and management corporation, five years as assistant electrical engineer. Available on short notice. C-9629.

METER OR TESTING ENGINEER, 29, B. S. in E. E., honors, standard university. Ten years' experience; utilities, standardization, meter, transmission, plant departments. Started reading meters. One year sales engineer, large instrument manufacturer. Good records and references. Qualified for industrial or utility construction, testing, or operation. Location immaterial. Will travel. Available immediately. C-9667.

ASSISTANT PROFESSOR OR INSTRUCTOR, Cornell graduate, diversified practical work, two and one-half years' teaching experience. Thoroughly familiar with present day practise in mechanical and electrical equipment for industrial and power work. A-3702.

ELECTRICAL ENGINEER, M. S. 1931 from M. I. T., 23, single. Summer xperience with American Tel. and Tel. Company. Desires position with electrical company preferably in research laboratory or as instructor in E. E mathematics, or physics. Available immediately. Location, East or Middle West. C-9674.

POSITION AS INSTRUCTOR OR ASSISTANT PROFESSOR in technical school for E. E. wanted. Age 28, degrees of S. B. S. M. in electrical engineering. Can handl classes in any phase of work relating to power plants, substations, radio distribution, or transmission. East preferred. Employed at present. C-5744.

GRADUATE ELECTRICAL ENGINEER, class 1926, Columbia, age 28, married. Practical experience with power company and telephone company. One year as laboratory assistant in electrical classes and three years as instructor in evening classes in college mathematics have aroused a sincere desire to make teaching life work, as instructor in E. E. mathematics, or physics. C-9308.

RELAY, CONTROL ENGINEER, 30, McGill graduate. Have done responsible engineering work planning relay applications, protective circuits, automatic, supervisory controls. Thoroughly familiar, equipment large generating, substations, use of laboratory facilities, field engineering methods. Valuabl experience, communication circuits, amplifiers, photoelectric cells, maintenance of highest standards in their circuits. Proved ability in personal contact. Location, Canada. C-4668.

1929 ELECTRICAL DESIGN ENGINEER, 24, B. S. degree technical school. One year Westinghouse student course. Motor, transformer, turbo test experience. One year large synchronous motor design. Six months Westinghouse electrical design school. Desires position; design, research, development work, manufacturing company, or engineering department power company. Single with dependents. Location, immaterial. References. Available immediately. C-9410.

Membership

Recommended for Transfer

The board of examiners, at its meeting of July 29, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

To Grade of Fellow

BURKHOLDER, CHARLES I., vice-pres., Duke Power Co., Charlotte, N. C.

CREIM, BENJAMIN W., chief elec. engr., Modesto Irrigation District, Modesto, Calif.

To Grade of Member

ALLEN, CLAYTON M., junior elec. eng., Dept. of Water and Power, Los Angeles, Calif.

BEAR, FRED T., elec. engr., Delaware Pr. & Light Co., Wilmington, Del.

BRAUN, ELMER H., junior engr., N. Y. & Queens Elec. Lt. & Pr. Co., Flushing, N. Y.

BUCK, O. KENDALL, supervising power salesman, Dept. of Water and Power, Los Angeles, Calif.

CRANE, CARL C., substation engr., Northern Indiana Public Service Co., Hammond, Indiana.

DAVIS, ARTHUR L., asst. gen'l. supt., Western Massachusetts Companies, Turners Falls, Mass.

DORMER, WILLIAM J. S., division toll-plant engr., Bell Telephone Co. of Canada, Montreal, Can.

DUNCAN, JAMES A., research engr., Brooklyn Edison Co., Inc., Brooklyn, N. Y.

EITMAN, JOSEPH F., design engr., General Electric Co., Fort Wayne, Indiana.

HARRIS, HIRAM D., instructor in E. E. and physics, Rensselaer Polytechnic Institute, Troy, N. Y.

HOLLADAY, WM. L., engg. mgr., The George Belsey Co. Ltd., Los Angeles, Calif.

KATZMAN, JACOB, elec. engr., Dubilier Clock Corp., New York.

LEE, Jr., STEWART, engg. dept., N. Y. Shipbuilding Co., Camden, N. J.

MOORE, LEONARD J., exec. engr., San Joaquin Lt. and Pr. Corp., Fresno, Calif.

MORGAN, THEODORE H., asst. prof. of E. E., Stanford University, Stanford University, Calif.

MOSER, FRED L., supt. of maintenance, Duke Power Co., Charlotte, N. C.

NAEF, OTTO, consulting engr., American Brown Boveri Co. Inc., Camden, N. J.

POLKINGHORN, FRANK ALLEN, member of tech. staff, Bell Telephone Laboratories Inc., New York.

RICHARDSON, HARVEY R., laboratory engr., Brooklyn Edison Co. Inc., Brooklyn, N. Y.

SCHULZE, RAYMOND C. R., assistant engr., Public Service Elec. & Gas Co., Newark, N. J.

SHADGETT, LAURENCE M., supt. wholesale operations, Georgia Power Co., Atlanta, Ga.

SHARP, HUBERT, transmission engr., Mountain States Tel. & Tel. Co., Denver, Colo.

SMITH, HUGH L., engr., General Electric Co., New York.

TUCKER, WILMER H., elec. engr., The Hoover Co., North Canton, Ohio.

WALSH, HOWARD A., field engr., Doble Engineering Co., Boston, Mass.

WOODS, JOHN C., designer, Commonwealth Edison Co., Chicago, Ill.

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before September 30, 1931.

Bantau, J. W., Paramount Publix Corp., Los Angeles, Calif.

Benson, A., Oklahoma A. & M. College, Stillwater, Okla.

Coleman, G. G., The Chesapeake & Potomac Tel. Co., Washington, D. C.

Cook, J. F., Jr., R. C. A. Victor Co., Jamaica Plain, Mass.

Cruickshank, J. P., Appalachian Electric Power Co., Huntington, W. Va.

Fricker, W. R., Canadian Westinghouse Co., Ltd., Regina, Sask., Can.

Hipp, R., Jr., Broad River Power Co., Pomaria, So. Car.

Inkster, O., Saskatchewan Power Commission, Regina, Sask., Canada

Ireland, G. (Member) American Tel & Tel. Co., New York, N. Y.

Jastram, R., Star Electric Motor Co., Newark, N. J.

Kurdy, S. M., Automobile Laundry Engineering Corp., Newark, N. J.

Levoy, L. G., Jr., General Electric Co., Schenectady, N. Y.

Lytle, C. M., Kansas City Pr. & Lt. Co., Kansas City, Mo.

Maessen, F. T., 412 City-Central Bldg., San Antonio, Tex.

Merrill, C. B., Bell Tel. Co. of Pa., Pittsburgh, Pa.

Moscato, F., Automatic Musical Inst. Co. of Grand Rapids, Mich., Central Park, L. I., New York.

Murphy, P. J., Dept. of Public Works, Essondale, B. C., Can.

Porter, F. C., United Elec. Lt. & Pr. Co., New York, N. Y.

Rees, J. B. (Member) American Tel. & Tel. Co., New York, N. Y.

Roberts, W. N., Box 15, Woodside, L. I., N. Y.

Rosenberger, G. L., Virginia Public Service Co., Alexandria, Virginia

Sanford, R. V. (Member) Tucson Gas, Elec. Lt. & Pr. Co., Tucson, Ariz.

Sharp, R. E. B., (Member), J. P. Morris & De La Vergne, Inc., Philadelphia, Pa.

Stoll, G. M., N. J. Bell Telephone Co., Asbury Park, N. J.

Thorne, E. C., Southern Canada Power Co., Drummondville, Que., Can.

Tingley, F. T. (Member) Clemson College, Clemson College, So. Carolina.

Valverde, R., Valverde Laboratory, New York, N. Y.

von Turffs, H., Montana Power Co., Bozeman, Mont.

Winkler, S. C. (Member) Los Angeles Junior College, Los Angeles, Calif.

Wright, R. B., United Electric Lt. & Pr. Co., New York, N. Y.

Wyman, A. W., Warren Telechron Co., Ashland, Mass.

31 Domestic

Foreign

Gillott, J. K. (Member) Metropolitan-Vickers Elec. Co., Trafford Park, Manchester, England

Stratton, T. P., DeBeers Cons. Mines, Ltd., Kimberley, S. Africa

Ratnam, G. M., Chola Power House, Dist. Thana, Bombay, India

Thomson, L. P., Estacion Lacroze, Buenos Aires, S. A.

September 1931

Order Form for Pamphlet Copies of A. I. E. E. Papers*

All papers presented at the 1931 Pacific Coast Convention

Number	Author	Title
☐ 31-122	C. C. Campbell and H. N. Kalb	Radio Coordination
☐ 31-123	C. E. Magnusson	The Kindling of Electric Sparkover
☐ 31-124	H. H. Skilling	Tuned Power Lines
☐ 31-125	E. M. Calderwood and D. F. Smith	The San Francisco-Los Angeles Section of The Pacific Coast Telephone Cable Networks
☐ 31-126	G. D. Floyd and J. R. Dunbar	Calorimeter Measurement of Stray-Load Losses of 55,000-Kva. Generator Having Enclosed System of Ventilation
☐ 31-127	T. E. Purcell and C. A. Powel	Tie-Line Control of Interconnected Networks
☐ 31-128	H. C. Hill and J. B. Se Legue	Electrical Equipment for Oil-Field Operation
☐ 31-129	J. J. Pilliod	Intercontinental Radiotelephone Service from the United States
☐ 31-130	E. A. Crellin	The Mokelumne River Development
☐ 31-131	E. M. Wright and B. D. Dexter	Power Transmission and Distribution From the Mokelumne River Development of the Pacific Gas and Electric Company
☐ 31M1	C. E. Carey and K. L. Howe	Electric Power in the Wood-Products Industry
☐ 31M2	S. B. Clark	A-C. Networks in Portland, Oregon
☐ 31M3	C. F. Green	Electrical Solutions of Problems of Regular Scheduled Flight
☐ 31M4	H. P. Boardman	Snow Surveys and Hydro-Forecasting
☐ 31M5	S. S. Mackeown	Cathode Drop in Arcs and Glow Discharges
☐ 31M6	A. L. Albert and W. R. Bullis	Electrical Measurements of Sound-Absorption
☐ 31M7	Vaino Hoover	Correlation of Induction Motor Design Factors

Papers presented prior to September 1931 upon which articles in this issue are based

Number	Author	Title
☐ 31-25	Philip Sporn and H. P. St. Clair	Oil Circuit Breaker Tests—Philo 1930, Aims, Set-up and Results From a System and Operating Viewpoint
☐ 31-26	R. M. Spurck and H. E. Strang	Circuit-Breaker Field Tests on Standard and Oil-Blast Explosion Chamber Oil Circuit Breakers
☐ 31-27	B. M. Pickens	Inclined-Catenary Calculations
☐ 31-39	R. C. Bergvall	Series Resistance Methods of Increasing Transient Stability Limits
☐ 31-51	N. F. Clement and E. E. Richards	Design of Catenary System for Cleveland Union Terminal
☐ 31-62	E. W. Griffith	Telegraph Power Plants

*Members, Enrolled Students, and subscribers are entitled to one pamphlet copy of any paper in this list if requested within one year from above date. Thereafter a charge of twenty-five cents per copy will obtain.

Officers and Committees for 1931-32

President

(Term expires July 31, 1932)
C. E. SKINNER

Junior Past-Presidents

(Term expires July 31, 1932)
HAROLD B. SMITH

(Term expires July 31, 1933)
W. S. LEE

Vice-Presidents

(Terms expire July 31, 1932)
H. V. CARPENTER (District No. 9)
G. C. SHAAD (District No. 7)
I. E. MOULTROP (District No. 1)
H.P. CHARLESWORTH (District No. 3)
T. N. LACY (District No. 5)

(Terms expire July 31, 1933)
A. W. COPLEY (District No. 8)
W. B. KOUWENHOVEN (District No. 2)
W. E. FREEMAN (District No. 4)
P. H. PATTON (District No. 6)
L. B. CHUBBUCK (District No. 10)

Directors

(Terms expire July 31, 1932)
J. ALLEN JOHNSON
A. M. MacCUTCHEON
A. E. BETTIS

(Terms expire July 31, 1933)
J. E. KEARNS
F. W. PEEK, JR.
C. E. STEPHENS

(Terms expire July 31, 1934)
A. B. COOPER
A. E. KNOWLTON
R. H. TAPSCOTT

(Terms expire July 31, 1935)
L. W. CHUBB
H. R. WOODROW
B. D. HULL

National Treasurer

(Term expires July 31, 1932)
W. I. SLICHTER

National Secretary

(Term expires July 31, 1932)
F. L. HUTCHINSON

General Counsel

PARKER & AARON
20 Exchange Place, New York, N. Y.

Local Honorary Secretaries

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.

H. W. Flashman, Aus. Westinghouse Elec. Co., Ltd., Cathcart House, 11 Castlereagh St., Sydney, N. S. W., Australia.

F. M. Servos, Rio de Janeiro Tramways Lt. & Pr. Co., Rio de Janeiro, Brazil, S. A.

A. P. M. Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.

A. S. Garfield, 173 Boulevard Haussmann, Paris (8e), France.

B. C. Battye, Punjab P. W. D., Hydroelectric Branch, Kapurthala House, Lahore, India.

Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.

P. H. Powell, Canterbury College, Christchurch, New Zealand.

M. A. Chatelain, Polytechnical Institute, Apt. 27, Leningrad, Sosnowka 1-3, U. S. S. R.

A. F. Enstrom, Ingeniorsvetenskapsakademien, Stockholm, 5, Sweden.

W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

GENERAL COMMITTEES

Executive Committee

C. E. Skinner, Chairman, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
H. P. Charlesworth,
J. A. Johnson,
W. S. Lee,
F. W. Peek, Jr.,
W. I. Slichter,
C. E. Stephens.

Board of Examiners

H. Goodwin, Jr., Chairman, 601 Franklin Bldg., Philadelphia, Pa.
H. E. Farrer, Secretary, 33 W. 39th St., New York, N. Y.
H. A. Currie,
H. W. Drake,
S. P. Grace,
H. A. Kidder,
F. V. Magalhaes,
R. H. Marriott,
L. W. W. Morrow,
A. L. Powell,
W. R. Smith,
S. D. Sprong,
R. H. Tapscott.

Finance Committee

C. E. Stephens, Chairman, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York, N. Y.
H. P. Charlesworth,
R. H. Tapscott,

Publication Committee

E. B. Meyer, Chairman, 80 Park Place, Newark, N. J.
F. A. Lewis, Secretary, 33 W. 39th St., New York, N. Y.
W. S. Gorsuch,
W. H. Harrison,
F. L. Hutchinson,
H. R. Woodrow.

Meetings and Papers Committee

W. H. Harrison, Chairman, Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.
C. S. Rich, Secretary, 33 W. 39th St., New York, N. Y.
V. Bush,
W. S. Gorsuch,
W. B. Kouwenhoven,
Paul MacGahan,
T. A. Worcester

Ex-officio

Chairman of Committee on Coordination of Institute Activities.

Chairman of Technical Committees.

Sections Committee

E. S. Lee, Chairman, General Electric Co., Schenectady, N. Y.
W. B. Kouwenhoven,
G. H. Quermann,
I. M. Stein,
W. H. Timbie.

Ex-officio

Chairmen of Sections.

Membership Committee

R. L. Kirk, Chairman, Duquesne Light Co., Pittsburgh, Pa.
E. P. Coles,
F. G. Graf,
J. Harrison,
V. L. Hollister,
J. A. Johnson,
C. H. Kline,
J. A. Koontz,
T. G. LeClair,
D. W. Proebstel,
I. M. Stein,
E. M. Wood.

Ex-officio

Chairmen of Section membership committees.

Law Committee

W. S. Gorsuch, Chairman, 600 West 59th Street, New York, N. Y.
C. O. Bickelhaupt,
H. A. Kidder,
E. B. Meyer,
W. I. Slichter.

Committee on Coordination of Institute Activities

H. P. Charlesworth, Chairman, 463 West Street, New York, N. Y.
W. S. Gorsuch,
W. H. Harrison,
F. L. Hutchinson,
E. S. Lee,
E. B. Meyer,
C. E. Stephens.

Committee on Student Branches

W. H. Timbie, Chairman, Massachusetts Institute of Technology, Cambridge, Mass.
W. E. Freeman,
F. O. McMillan,
C. F. Scott,
W. J. Seeley.

Ex-officio

Student Branch Counselors.

Headquarters Committee

R. H. Tapscott, Chairman, New York Edison Co., 4 Irving Place, New York, N. Y.
F. L. Hutchinson,
C. E. Stephens.

Public Policy Committee

B. Gherardi, Chairman, Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.
C. C. Chesney,
F. B. Jewett,
W. S. Lee,
F. Osgood,
H. J. Ryan,
R. F. Schuchardt.

Standards Committee

A. M. MacCutcheon, Chairman, Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.
H. E. Farrer, Secretary, 33 W. 39th St., New York, N. Y.
A. B. Cooper,
J. E. Goodale,
C. R. Harte,
J. F. Meyer,
V. M. Montsinger,
F. D. Newbury,
L. T. Robinson,
W. I. Slichter.

Ex-officio

Chairmen of Working Committees.

Chairmen of A. I. E. E. delegations and representatives on other standardizing bodies.

President of U.S. National Committee of I. E. C.

Edison Medal Committee

Appointed by the President for term of five years.

(Terms expire July 31, 1932)
H. P. Charlesworth,
P. M. Lincoln,
C. E. Stephens.

(Terms expire July 31, 1933)
D. C. Jackson, Chairman.
C. F. Harding,
F. A. Scheffler.

(Terms expire July 31, 1934)
L. W. W. Morrow,
W. S. Rugg,
R. F. Schuchardt.

(Terms expire July 31, 1935)
C. I. Burkholder,
F. A. Gaby,
H. J. Ryan.

(Terms expire July 31, 1936)
E. B. Meyer,
L. T. Robinson,
P. H. Thomas.

Appointed by the Board of Directors from its own membership for term of two years.

(Terms expire July 31, 1932)
A. E. Knowlton,
H. B. Smith,
R. H. Tapscott.

(Terms expire July 31, 1933)
J. E. Kearns,
W. S. Lee,
F. W. Peek, Jr.

Ex-officio

(Terms expire July 31, 1932)
C. E. Skinner, President,
W. I. Slichter, National Treasurer,
F. L. Hutchinson, National Secretary.

Lamme Medal Committee

(Terms expire July 31, 1932)
C. C. Chesney, Chairman.
H. P. Charlesworth,
R. B. Williamson.

(Terms expire July 31, 1933)
R. D. Mershon,
J. C. Smith,
P. H. Thomas.

(Terms expire July 31, 1934)
B. A. Behrend,
A. M. Dudley,
J. C. Parker.

Committee on Code of Principles of Professional Conduct

R. F. Schuchardt, Chairman, 72 West Adams Street, Chicago, Ill.

A. H. Babcock,
G. Faccioli,
F. B. Jewett,
W. E. Mitchell,
C. E. Stephens,
J. B. Whitehead.

Committee on Award of Institute Prizes

W. H. Harrison, Chairman, Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.

L. W. Chubb,
A. E. Knowlton,
E. B. Meyer.

Committee on Safety Codes

J. C. Forsyth, Chairman, New York Board of Fire Underwriters, 85 John Street, New York, N. Y.

A. W. Berresford,
L. B. Chubbuck,
J. F. Fairman,
H. B. Gear,
F. D. Knight,
M. G. Lloyd,
Wills Maclachlan,
F. V. Magalhaes,
J. D. Noyes,
F. A. Pattison,
H. R. Sargent,
Frank Thornton,
H. S. Warren.

Committee on Columbia University Scholarships

W. I. Slichter, Chairman, Columbia University, New York.

F. Blossom,
H. C. Carpenter.

Committee on Legislation Affecting the Engineering Profession

H. A. Kidder, Chairman, 600 West 59th Street, New York, N. Y.

J. P. Alexander,
T. F. Barton,
B. M. Brigman,
H. P. Charlesworth,
L. F. Leurey,
L. W. W. Morrow,
J. C. Parker,
J. R. Price,
H. S. Sands,
M. R. Scharff,
H. H. Schoolfield,
W. I. Slichter,
J. B. Thomas.

Committee on the Economic Status of the Engineer

C. O. Bickelhaupt, Chairman, Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.

W. S. Lee,
E. W. Rice, Jr.,
W. S. Rugg,
C. F. Scott.

Advisory Committee to the Museum of Science and Industry in the City of New York

J. P. Jackson, Chairman, New York Edison Co., 4 Irving Place, New York, N. Y.

C. O. Bickelhaupt,
R. H. Nexsen.

Committee on Popular Science Award

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.

W. H. Harrison,
C. E. Stephens.

TECHNICAL COMMITTEES

Automatic Stations

D. W. Taylor, Chairman, United Engineers & Constructors, Inc., 80 Park Place, Newark, N. J.

F. F. Ambuhl,
L. D. Bale,
C. W. Colvin,
C. F. Craig,
A. M. Garrett,
Joseph Hellenthal
Chester Lichtenberg,
C. A. Mayo,
I. E. Moultrop,
M. E. Reagan,
O. J. Rotty,
Garland Stamper,
L. J. Turley,
F. Zogbaum.

Communication

H. S. Osborne, Chairman, Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.

H. M. Bascom,
E. L. Bowles,
W. H. Capen,
A. A. Clokey,
R. N. Conwell,
C. F. Craig,
B. R. Cummings,
I. C. Forshee,
D. H. Gage,
B. D. Hull,
G. M. Keenan,
G. A. Kositzky,
C. J. Larsen,
John Mills,
J. W. Milnor,
E. J. O'Connell,
Frederick A. Raymond,
H. A. Shepard,
Emmett R. Shute,
A. L. Stadermann,
C. H. Taylor,
H. M. Turner,
F. A. Wolff.

Education

R. E. Doherty, Chairman, Yale University, New Haven, Conn.

R. W. Adams,
M. W. Alexander,
E. W. Allen,
J. W. Barker,
Edward Bennett,
P. S. Biegler,
H. V. Carpenter,
C. S. Coler,
C. R. Dooley,
H. E. Dyche,
O. W. Eshbach,
O. J. Ferguson,
H. H. Henline,
A. H. Lovell,
H. W. Price,
W. T. Ryan,
G. B. Thomas,
W. H. Timbie,
W. E. Wickenden.

Electrical Machinery

P. L. Alger, Chairman, General Electric Co., Schenectady, N. Y.

B. L. Barns,
E. S. Bundy,
H. E. Edgerton,
J. E. Goodale,
T. T. Hambleton,
A. L. Harding,
C. F. Harding,
E. W. Henderson,
S. L. Henderson,
L. F. Hickernell,
J. A. Johnson,
J. J. Linebaugh,
H. C. Louis,
A. M. MacCutcheon,
O. K. Marti,
V. M. Montsinger,
E. L. Moreland,
R. W. Owens,
R. H. Park,
E. B. Paxton,
H. V. Putnam,
K. A. Reed,
A. M. Rossman,
O. E. Shirley,
R. G. Warner,
C. A. M. Weber,
R. B. Williamson.

Electric Welding

P. P. Alexander, Chairman, General Electric Co., River Works, West Lynn, Mass.

C. A. Adams,
A. M. Candy,
Alexander Churchward,
F. Creedy,
S. Dushman,
K. L. Hansen,
H. M. Hobart,
R. G. Hudson,
J. E. Kearns,
J. C. Lincoln,
Ernest Lunn,
F. C. Owen,
J. Slepian,
W. Spraragen,
H. E. Stoddard,
H. W. Tobey,
G. H. Winkler.

Electrochemistry and Electrometallurgy

(To be appointed)

Electrophysics

V. Bush, Chairman, Mass. Inst. of Tech., Cambridge A, Mass.

O. E. Buckley,
W. G. Cady,
W. F. Davidson,
L. O. Grondahl,
W. B. Kouwenhoven,
B. E. Lenehan,
G. M. J. Mackay,
S. S. Mackeown,
K. B. McEachron,
L. W. McKeehan,
H. Nyquist,
J. Slepian.
W. C. White.

Liaison Representatives of American Physical Society

Prof. Leigh Page,
Dr. W. F. G. Swann.

General Power Applications

C. W. Drake, Chairman, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

A. H. Albrecht,
E. A. Armstrong,
James Clark, Jr.,
J. F. Gaskill,
John Grotzinger,
T. Hibbard,
Fraser Jeffrey,
A. M. MacCutcheon,
H. A. Maxfield,
John Morse,
N. L. Mortensen,
A. M. Perry,
D. M. Petty,
H. W. Rogers,
L. D. Rowell,
W. K. Vandorpool,
M. R. Woodward.

Instruments and Measurements

E. J. Rutan, Chairman, New York Edison Co., 92 Vandam Street, New York, N. Y.

H. S. Baker,
O. J. Bliss,
P. A. Borden,
H. B. Brooks,
A. L. Cook,
E. D. Doyle,
W. W. Eberhardt,
Marion Eppley,
J. B. Gibbs,
W. N. Goodwin, Jr.,
I. F. Kinnard,
O. A. Knopp,
A. E. Knowlton,
H. C. Koenig,
W. B. Kouwenhoven,
F. A. Laws,
E. S. Lee,
J. B. Lunsford,
Paul MacGahan,
R. T. Pierce,
W. J. Shackelton,
H. L. Thomson,
H. M. Turner.

Applications to Iron and Steel Production

A. C. Cummins, Chairman, Carnegie Steel Co., Duquesne, Pa.

F. B. Crosby,
Wray Dudley,
J. E. Fries,
S. L. Henderson,
A. M. MacCutcheon,
F. O. Schnure,
W. B. Shirk,
G. E. Stoltz,
T. S. Towle,
H. A. Winne.

Production and Application of Light

W. T. Blackwell, Chairman, 80 Park Place, Newark, N. J.

J. W. Barker,
A. E. Bettis,
H. S. Broadbent,
J. M. Bryant,
W. T. Dempsey,
R. E. Dorting,
L. A. Hawkins,
H. H. Higbie,
C. L. Kinsloe,
R. D. Mailey,
G. S. Merrill,
P. S. Millar,
P. H. Moon,
C. M. Moss,
R. E. Simpson,
G. H. Stickney.

Applications to Marine Work

R. A. Beekman, Chairman, General Electric Co., Schenectady, N. Y.

E. C. Alger,
H. C. Coleman,
E. M. Glasgow,
H. F. Harvey, Jr.,
C. J. Henschel,
W. Hetherington, Jr.,
H. L. Hibbard,
J. E. Kearns,
A. Kennedy, Jr.,
J. B. Lunsford,
I. H. Osborne,
G. A. Pierce,
W. H. Reed,
E. P. Slack,
H. M. Southgate,
W. E. Thau,
John Van der Dussen,
A. E. Waller,
O. A. Wilde,
C. L. Wilson,
R. L. Witham,
W. N. Zippler.

Applications to Mining Work

D. E. Renshaw, Chairman, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

A. R. Anderson,
Graham Bright,
J. H. Edwards,
E. J. Gealy,
L. C. Ilsley,
J. E. Kearns,
Carl Lee,
W. H. Lesser,
C. W. Parkhurst,
F. L. Stone,
J. F. Wiggert,
C. D. Woodward.

Power Generation

J. R. Baker, Chairman, 1611 Lexington Building, Baltimore, Md.

F. A. Allner,
F. A. Annett,
D. S. Brown,
A. Carnegie,
H. E. Clifford,
J. B. Crane,
B. D. Dexter,
R. D. DeWolf,
W. P. Dryer,
N. E. Funk,
W. S. Gorsuch,
F. C. Hanker,
L. F. Harza,
J. V. L. Hogan,
F. H. Hollister,
A. H. Hull,
H. W. Leitch,
A. N. Lovell,
E. B. Meyer,
I. E. Moultrop,
F. A. Scheffler,
F. O. Schnure,
A. E. Silver,
Arthur R. Smith.

Power Transmission and Distribution

P. H. Chase, Chairman, Philadelphia Electric Co., 900 Sansom Street, Philadelphia, Pa.

Sydney Alling,
E. J. Amberg,
F. E. Andrews,
A. B. Campbell,
C. V. Christie,
R. N. Conwell,
A. E. Davison,
H. C. Dean,
L. L. Elden,
R. D. Evans,
F. M. Farmer,
Edwin Hansson,
K. A. Hawley,
L. F. Hickernell,
D. C. Jackson, Jr.,

INSTITUTE REPRESENTATIVES

Aeronautic Radio Research, Liaison Committee on

Ray H. Manson.

Alfred Noble Prize Committee

A. E. Knowlton.

American Association for the Advancement of Science Council

L. M. Klauber, C. E. Skinner.

American Bureau of Welding

H. M. Hobart.

American Committee on Electrolysis

B. J. Arnold, N. A. Carle,
F. N. Waterman.

American Engineering Council Assembly

A. W. Berresford,
*C. O. Bickelhaupt,
F. J. Chesterman,
M. M. Fowler,
F. L. Hutchinson,
*H. A. Kidder,
W. S. Lee,
William McClellan,
L. F. Morehouse,
I. E. Moultrop,
Farley Osgood,
W. S. Rodman,
*R. F. Schuchardt,
*Charles F. Scott,
*C. E. Skinner,
Harold B. Smith,
C. E. Stephens,
L. B. Stillwell.

*Representatives on Administrative Board.

American Marine Standards Committee

R. A. Beekman.

American Standards Association Board of Directors

B. Gherardi.

Council

F. D. Newbury, John C. Parker,
L. T. Robinson.

Alternates

H. H. Henline, H. M. Hobart,
H. S. Osborne.

American Year Book, Advisory Board

Henry H. Henline.

Charles A. Coffin Fellowship and Research Fund Committee

C. E. Skinner.

Committee of Apparatus Makers and Users, National Research Council

L. T. Robinson.

Committee on Elimination of Fatigue, Society of Industrial Engineers

C. Francis Harding.

Committee on Heat Transmission, National Research Council

T. S. Taylor.

Electrical Standards Committee, A. S. A.

H. P. Charlesworth, F. D. Newbury,
L. T. Robinson.

Engineering Foundation Board

C. E. Skinner, W. I. Slichter.

Engineering Societies Monographs Committee

E. B. Meyer, W. I. Slichter.

Hoover Medal Board of Award

Gano Dunn, F. B. Jewett,
E. W. Rice, Jr.

John Fritz Medal Board of Award

Bancroft Gherardi, R. F. Schuchardt,
W. S. Lee, Harold B. Smith.

Joint Committee on Welded Rail Joints

D. D. Ewing.

Joint Conference Committee of Founder Societies

The Presidents and Secretaries, *ex-officio*.

Library Board, United Engineering Trustees, Inc.

W. S. Barstow, F. L. Hutchinson,
W. A. Del Mar, W. B. Jackson,
W. I. Slichter.

National Fire Protection Association, Electrical Committee

J. C. Forsyth, F. V. Magalhaes,
Alternate.

National Fire Waste Council

J. C. Forsyth, F. V. Magalhaes.

National Research Council, Engineering Division

H. P. Charlesworth, F. W. Peek, Jr.,
C. E. Skinner.
F. L. Hutchinson, *ex-officio.*

National Safety Council, A. S. S. E.—Engineering Section

J. C. Forsyth.

Radio Advisory Committee, Bureau of Standards

A. E. Kennelly.

United Engineering Trustees, Inc., Board of Trustees

H. P. Charlesworth, H. A. Kidder,
G. L. Knight.

U. S. National Committee of the International Commission on Illumination

A. E. Kennelly, C. O. Mailloux,
Clayton H. Sharp.

U. S. National Committee of the International Electrotechnical Commission

L. F. Adams,
E. W. Allen,
James Burke,
W. A. Del Mar,
Gano Dunn,
F. C. Hanker,
C. R. Harte,
H. M. Hobart

Commission of Washington Award

L. A. Ferguson, Charles F. Scott.

Geographical District Executive Committees

District	Chairman (Vice-President, A. I. E. E.)	Secretary (District Secretary)
No. 1—North Eastern	I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston, Mass.	A. C. Stevens, General Electric Co., Schenectady, N. Y.
No. 2—Middle Eastern	W. B. Kouwenhoven, Johns Hopkins University, Baltimore, Md.	George S. Diehl, Pennsylvania Water & Power Co., 1611 Lexington Building, Baltimore, Md.
N . 3—New York City	H. P. Charlesworth, 463 West St., New York, N. Y.	C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York, N. Y.
No. 4—Southern	W. E. Freeman, University of Kentucky, Lexington, Ky.	E. A. Bureau, University of Kentucky, Lexington, Ky.
No. 5—Great Lakes	T. N. Lacy, Mich. Bell Tel. Co., 1365 Cass Ave., Detroit, Mich.	A. G. Dewars, No. States Pr. Co., 15 S. 15th St., Minneapolis, Minn.
No. 6—North Central	P. H. Patton, Northwestern Bell Tel. Co., Telephone Building, Omaha, Neb.	M. S. Coover, University of Colorado, Boulder, Colo.
No. 7—South West	G. C. Shaad, University of Kansas, Lawrence, Kans.	R. W. Warner, University of Kansas, Lawrence, Kans.
No. 8—Pacific	A. W. Copley, Westinghouse Elec. & Mfg. Co., 1 Montgomery St., San Francisco, Calif.	C. E. Baugh, 245 Market St., San Francisco, Calif.
No. 9—North West	H. V. Carpenter, State College of Washington, Pullman, Wash.	R. D. Sloan, State College of Washington, Pullman, Wash.
No. 10—Canada	L. B. Chubbuck, Canadian Westinghouse Co., Hamilton, Ont.	W. L. Amos, Hydro-Elec. Pr. Com., 190 University Ave., Toronto, Ont.

Note: Each District Executive Committee includes the chairmen and secretaries of all Sections within the District and the chairman of the District Committee on Student Activities.

Local Sections of the Institute

Name	District	Chairman	Secretary	Secretary's Address
Akron	2	R. R. Krammes	R. A. Hudson	Goodyear Zeppelin Corp., Akron, Ohio
Atlanta	4	A. G. Stanford	J. H. Persons	General Electric Co., Atlanta, Ga.
Baltimore	2	K. A. Hawley	J. Wells	Western Electric Co., Baltimore, Md.
Birmingham	4		O. E. Charlton	Allied Engineers, Inc., Birmingham, Ala.
Boston	1	C. A. Corney	G. J. Crowdes	Simplex Wire & Cable Co., Cambridge, Mass.
Chicago	5	F. R. Innes	E. C. Williams	20 North Wacker Drive, Chicago, Ill.
Cincinnati	2	E. S. Fields	J. A. Noertker	Cincinnati Street Railway Co., Cincinnati, Ohio
Cleveland	2	G. A. Kositzky	F. E. Snell	Cleveland Railway Co., Cleveland, Ohio
Columbus	2	W. L. Everitt	Roy Mallory	Ohio Bell Tel. Co., Columbus, Ohio
Connecticut	1	R. G. Warner	W. B. Hall	Yale University, New Haven, Conn.
Dallas	7	Gibbs A. Dyer	S. M. Sharp	1100 Allen Bldg., Dallas, Tex.
Denver	6	R. E. Nyswander	N. R. Love	807 Tramway Bldg., Denver, Colo.
Detroit-Ann Arbor	5	J. J. Shoemaker	O. E. Hauser	Detroit Edison Co., Detroit, Mich.
Erie	2	P. R. Urich	C. V. Roberts	Erie Lighting Co., 21-23 West 10th St., Erie, Pa.
Florida	4	Joseph Weil	R. P. Smith	P. O. Box 2574, Jacksonville, Fla.
Fort Wayne	5	E. J. Schaefer	C. M. Summers	General Elec. Co., Fort Wayne, Ind.
Houston	7	E. M. Wise	J. S. Waters	Rice Institute, Houston, Texas
Indianapolis-Laf	5	E. L. Carter	E. G. Thoms	Indiana Bell Tel. Co., Indianapolis, Ind.
Iowa	5	H. B. Hoffhaus	E. W. Schilling	Iowa State College, Ames, Iowa
Ithaca	1	W. E. Meserve	B. K. Northrop	Cornell Univ., Ithaca, N. Y.
Kansas City	7	George Fiske	R. M. Ryan	General Electric Co., Kansas City, Mo.
Lehigh Valley	2	Morland King	J. H. Diefenderfer	Penna. Pr. & Lt. Co., Hazleton, Pa.
Los Angeles	8	P. S. Biegler	F. E. Dellinger	Los Angeles Gas & Elec. Corp., Los Angeles, Calif.
Louisville	4	P. P. Ash	C. M. Ewing	Louisville Gas & Elec. Co., Louisville, Ky.
Lynn	1	J. A. Cook	G. R. Sturtevant	General Electric Co., Lynn, Mass.
Madison	5	N. H. Blume	G. F. Tracy	University of Wisconsin, Madison, Wis.
Memphis	4	M. Eldredge	W. A. Gentry	Memphis Power & Light Co., Memphis, Tenn.
Mexico	3	B. F. Arias	L. Castro, Jr.	Departamento Electricidad y Telegrafos, Ferrocarriles Nacionales de Mex., Mexico, D. F.
Milwaukee	5	C. H. Krueger	E. U. Lassen	Cutler Hammer, Inc., Milwaukee, Wis.
Minnesota	5	Oscar Gaarden	E. H. Hagensick	The Pyle-National Co., St. Paul, Minn.
Nebraska	6	A. L. Turner	C. Talsma	610 Electric Building, Omaha, Nebraska
New York	3	O. H. Caldwell	H. C. Dean	N. Y. & Queens Elec. Lt. & Pr. Co., Flushing, N. Y.
Niagara Frontier	1	R. W. Graham	G. W. Eighmy	General Electric Co., 1100 Electric Bldg., Buffalo, N. Y.
North Carolina	4	J. H. Paget	F. C. DeWeese	Carolina Pr. & Lt. Co., Raleigh, N. C.
Oklahoma City	7	C. T. Almquist	C. E. Bathe	Oklahoma Gas & Elec. Co., Oklahoma City, Okla.
Philadelphia	2	C. N. Johnson	J. L. MacBurney	Elec. Storage Battery Co., Philadelphia, Pa.
Pittsburgh	2	F. A. Conner	T. Spooner	Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Pittsfield	1	F. R. Finch	K. B. Van Tassel	General Electric Co., Pittsfield, Mass.
Portland, Ore.	9	R. J. Davidson	F. M. Lewis	Northwestern Electric Co., Public Serv. Bldg., Portland, Ore.
Providence	1	W. S. Maddocks	O. W. Briden	Blackstone Valley Gas & Elec. Co., Pawtucket, R. I.
Rochester	1	F. C. Young	E. K. Huntington	Rochester Gas & Elec. Corp., Rochester, N. Y.
St. Louis	7	C. H. Kraft	C. H. Lankford	Century Electric Co., 1806 Pine St., St. Louis, Mo.
San Antonio	7	J. E. Woods	D. E. Woods	P. O. Box 1105, San Antonio, Texas
San Francisco	8	E. A. Crellin	W. C. Smith	872 Russ Bldg., San Francisco, Calif.
Saskatchewan	10	W. T. Hunt	A. B. Coward	Light & Power Dept., Regina, Sask., Can.
Schenectady	1	R. A. Beekman	E. P. Nelson	General Electric Co., Schenectady, N. Y.
Seattle	9	M. T. Crawford	C. B. Carpenter	Pacific Tel. & Tel. Co., Dexter Horton Bldg., Seattle, Wash.
Sharon	2	R. M. Field	A. M. Wiggins	Westinghouse E. & M. Co., Sharon, Pa.
Southern Virginia	4	J. H. Berry	E. L. Lockwood	Virginia Public Service Co., Newport News, V .
Spokane	9	H. L. Vincent	W. M. Allen	Home Tel. & Tel. Co., Spokane, Wash.
Springfield, Mass	1	B. V. K. French	L. C. Packer	Westinghouse Elec. & Mfg. Co., Springfield, Mass.
Syracuse	1	C. W. Henderson	W. E. Mueller	Denison & Thompson, Syracuse, N. Y.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during July are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

Business Adrift. By W. B. Donham. N. Y., McGraw-Hill Book Co., 1931. 165 pp., 9 x 6 in., cloth, $2.50.——A thoughtful, important contribution upon the problems that threaten our future economic well-being. The author discusses the part that business men must play in meeting the needs of the American people, and offers a plan for the future which will meet changing business conditions intelligently.

Aircraft Yearbook, 1931. Edit. by Aeronautical Chamber of Commerce. N. Y., D. Van Nostrand Co., 1931 607 pp., illus., diagrs., charts, maps, tables, 9 x 6 in., cloth, $6.00.——Reviews technical and commercial developments during the year. Describes the air lines in operation and the work of the army and navy, the activities of colleges, the changes in airplane design, legislation, etc. Drawings of all aircraft and engines in production are given, together with much statistical information.

Abfluss-Untersuchungen und-Berechnungen für Ueberfälle an Scharfkantigen Wehren. (Mitteilungen aus dem Gebiete des Wasserbaues und der Baugrundforschung, Heft 4.) By C. Keutner. Berlin, W. Ernst & Sohn, 1931. 27 pp., illus., diagrs., 11 x 7 in., paper, 4.20-r. m.——Gives the results of observations of flow phenomena over weirs in glass channels and of experiments to find equations for the flow which will be accurate in cases where the usual equations fail. Rehbock's formula is found correct for certain conditions; other formulas are developed for special cases.

Elements of Thermodynamics. By Ernest M. Fernald. N. Y., McGraw-

Hill Book Co., 1931. 329 pp., charts, diagrs., tables, 9 x 6 in., cloth. $3.50.——Professor Fernald's aim is to give the student an adequate, flexible technique for dealing quantitatively with various situations, and sufficient data for meeting the simpler ones; together with clear ideas of the limitations that universal laws impose upon engineering practise, and of the conditions that practise must meet before finally perfected. The properties, processes, and cycles of steam and perfect gases, compressed air, refrigeration, evaporation and flow through nozzles, etc., are discussed.

Practical Radio including Television. 4th edit. By J. A. Moyer and J. F. Wostrel. N. Y., McGraw-Hill Book Co., 1931. 410 pp., illus., diagrs., charts tables, 8 x 5 in., cloth, $2.50.——A popular exposition of the principles of radio and of the usual types of receiving apparatus. Advice on the selection and operation of receivers is given and also upon the construction and testing of some typical sets. This edition has a new chapter on television as well as numerous revisions and corrections.

Practical Marine Diesel Engineering. 2nd edit. By L. R. Ford. N. Y., Simmons Boardman Publ. Co., 1931. 758 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth. $7.00.——Discusses construction and operation from the point of view of the practical engineer. Theoretical principles are explained briefly, the construction of the various parts of engines and the accessory equipment described, and detail given for a large number of makes of engines. A major portion of the book is devoted to operation, such matters as repairs, tests, and lubrication being explained quite fully.

Berechnungsgrundlagen und Konstruktive Ausbildung von Einlaufspirale und Turbinensaugrohr bei Niederdruckanlagen. By H. Rohde. Berlin, J. Springer, 1931. 112 pp., illus., diagrs., charts, tables, 10 x 6 in., paper, 11 r. m.——The design and construction of these important elements of a power plant are both hydraulic and mechanical problems, and the present book is intended to throw light upon the structural and mechanical phases of the subject. The study is intended to assist in determining the most efficient forms, with due attention to both hydraulic and structural considerations.

Aerial and Marine Navigation Tables. By J. E. Gingrich. N. Y., McGraw-Hill Book Co., 1931. 63 pp., diagrs., tables, 11 x 7 in., leather, $2.50. ——The aim of the compiler of these tables has been to combine speed, facility in use, and simplicity with accuracy. A uniform plan in the solution of all sights has been adopted, and the volume is usable over a wide range and of handy size. The tables are rearrangement of those devised by Doctor Ogura of the Japanese Navy.

Electrical Engineering. By C. V. Christie. N. Y., McGraw-Hill Book Co., Inc., 1931. 662 pp., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.——The fourth edition of this well-known text preserves the characteristics of former issues, but certain additions have been made, including an outline of the mathematical relations required for solving problems in a-c. theory, the design of a commutating-pole d-c. generator, a discussion of the problem of system stability, and a set of typical problems.

L'Emploi des Unités dans la Pratique des Calculs. By F. Bétrancourt. Paris, Dunod, 1931. 91 pp., tables, 9 x 6 in., paper, 16 frs.——A collection of the geometrical, mechanical, electrical, magnetic, and optical units of measurement, with definitions, formulas, etc., intended to aid calculators.

Experimental Radio Engineering. By J. H. Morecroft. N. Y., John Wiley & Sons, 1931. 345 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $3.50.——A laboratory course in the principles of radio, listing fifty-one experiments and designed to bring out characteristics of component parts of receiving and transmitting apparatus; the introduction is upon laboratory apparatus.

Sags and Tensions in Overhead Lines. By C. G. Watson. London & N. Y., Isaac Pitman & Sons, 1931. 192 pp., diagrs., charts, tables, 9 x 6 in., cloth, $3.75.——Presenting simple accurate methods for determining these sags and tensions, and requiring no further mathematical knowledge than an ability to plot and read graphs, and perform simple arithmetical operations. All the cases ordinarily met in practise are discussed and explained. Tables and graphs of hyperbolic and catenarian functions and a table of tangents are given.

Vector Analysis. By L. R. Shorter. London & N. Y., Macmillan & Co., 1931. 356 pp., diagrs., 8 x 5 in., cloth, $2.75.——The extensive use of vector methods in modern text-books of physics makes it necessary for the student of mathematical physics to have a working knowledge of vector analysis. This brief text is intended to supply that need. It is suited also for use as an introduction to the subject for students of mathematics.

Seeing, A Partnership of Lighting and Vision. By M. Luckiesh and F. K. Moss. Baltimore, Williams & Wilkins Co., 1931. 241 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.——Seeing depends upon light and lighting as well as upon the visual sense; yet light and lighting have not yet received much consideration as a partner of the visual sense, the authors assert, although excellent scientific data pertaining to vision are available. The present book aims to remedy this lack, in part, by giving the results of extensive research work, covering some 20 years of effort to establish the scientific principles of seeing. A bibliography is included.

Foundations of Radio. By Rudolph L. Duncan. N. Y., John Wiley & Sons, Inc., 1931. 246 pp., illus., diagrs., tables, 8 x 6 in., cloth, $2.50.——An introductory text-book on electricity covering in non-mathematical language the fundamentals of interest to students of radio engineering.

Mitteilungen aus den Forschungsanstalten, GHH-Konzern, Bd. 1, Heft 5, pp. 101-122, May 1931. Berlin, V. D. I. Verlag. Illus., diagrs., charts, tables, 12 x 9 in., paper, 3 r. m.——The first article in this bulletin discusses the use of large diesel engines in electric power plants. Their advantages for peak-load service and as standbys are shown. The bulletin also reports on investigations of methods of drying wood and their effects upon its mechanical properties.

Nature of a Gas. By L. B. Loeb. N. Y., John Wiley & Sons, 1931. 153 pp., diagrs., charts, tables, 9 x 6 in., cloth, $2.50.——Students and engineers interested in the behavior of dielectrics as insulation will be grateful for this review of the nature and electric properties of a gas afforded by this monograph. The structure of the molecule is discussed, and its behavior under various temperature conditions considered. The monograph is the first of a series sponsored by the committee on electrical insulation of the Division of Engineering and Industrial Research, National Research Council.

Die Anwendung der Nomographie in der Mathematik. By H. Schwerdt. Berlin, J. Springer, 1931. 116 pp., charts, diagrs., tables, 10 x 6 in., cloth. 28 r. m.——This book contains 104 charts containing 236 nomographs of various mathematical formulas, which illustrate the possibilities of nomographic methods in mathematics. The text explains the charts and shows how they may be used. A brief bibliography is included.

International Critical Tables of Numerical Data, Physics, Chemistry and Technology. v. 7. By the National Research Council. N. Y. McGraw-Hill Book Co., 1930. 507 pp., 11 x 9 in., cloth $84.00 (7 v).——This is the final volume of the work in which the best values for an immense number of constants and numerical data of physics, chemistry, and engineering are recorded for the convenience of research workers. The values are based upon all recorded work previous to 1924, as in the "Annual Tables of Constants and Numerical Data." The values given in the present work have been chosen by competent authorities as the most satisfactory. References to original publications are included. Indispensable in research laboratories and libraries of science.

Onward Industry! By J. D. Mooney and A. C. Reiley. N. Y. & London, Harper & Brothers, 1931. 564 pp., 10 x 6 in., cloth, $6.00.——An endeavor to discover and define the principles of efficient organization, by studying principles used by great political, military, and ecclesiastical organizations of the past. A historical review of human experience with large organizations, accompanied by a study of present coordination and operation problems in modern industrial corporations.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Selected Items From

Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Busbars

PROTECTION. Differential-Bus Protection Proves Its Merit, H. H. Cox. *Elec. World*, vol. 98, no. 1, July 4, 1931, p. 30, 2 figs. Inasmuch as station bus failures are always of serious nature it was realized by engineers of Department of Water and Power of city of Los Angeles that some form of bus protection was essential; original scheme of differential bus protection was proposed by author which involved connecting in parallel of as many current transformer secondaries as there were connections to bus in question.

Cables

INSULATION. Cable Insulation Thickness Can be Reduced, D. W. Roper. *Elec. World*, vol. 98, no. 1, July 4, 1931, pp. 27-29, 6 figs. Number of questions arose in connection with development of transmission system in Chicago region, such as maximum economical size for 132-kv. cable, feasibility of 220-kv. cable and economics of use of oil-filled cable for 60 kv. or lower voltages; some preliminary studies had indicated that most economical cable for given set of conditions would be determined by annual charges rather than by first cost, and this led to decision to extend investigations in progress so as to cover entire range of transmission voltages. Before Am. Inst. Elec. Engrs.

OIL-FILLED. The Theory of Oil-Filled Cable—I, G. B. Shanklin and F. H. Buller. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 416-420, 8 figs. Purpose of article is to round out general theory of high-tension oil-filled cable and describe additional development of important nature that have not yet been dealt with in technical press; article is sequent to recent A. I. E. E. paper by same authors "Characteristics of Oil-Filled Cable," two publications give fairly complete summary of latest oil-filled cable practise developed by General Electric Co.

Circuit Breakers

Influence de la forme de la tension de rupture sur le travail des disjoncteurs (Influence of Breaking Voltage Wave Form on Performance of Circuit Breakers), J. Kopeliowitch. *Association Suisse des Electriciens—Bul.*, vol. 22, no. 13, June 26, 1931, pp. 312-317, 8 figs. Comparative study of values obtained in cathode ray oscillographic research in 132-kv. lines of Ohio networks and in tests at high tension laboratory of Brown Boveri, Baden. Bibliography.

Clocks

ELECTRIC. Electric Clocks, F. Hope-Jones. Lond., N. A. G. Press, 1931, 261 pp., diagrs., 12 s. 6d. Combination historical and technical account of evolution of electric clock; starting with Alexander Bain's patent of 1840, author describes and criticizes efforts of successive inventors and illustrates steps that have led to highly accurate devices of today; numerous diagrams add to usefulness of book. Eng. Soc. Lib., N. Y.

Condensers

SYNCHRONOUS. Automatic Synchronous Condensers of the Washington Water Power Company, E. Baughn. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 421-424, 4 figs. Operate on 110-kv. lines; two machines, 7,500 kva. and 10,000 kva.; purpose to increase capacity and improve voltage regulation of lines; automatic control equipment; its functions and operation under normal and abnormal conditions.

Dielectrics

Dielectric Properties and Chemical Constitution, S. O. Morgan. *Bell Laboratories Rec.*, vol. 9, no. 11, July 1931, pp. 535-542, 9 figs. Atomic study.

Diesel-Electric

POWER PLANTS, AUTOMATIC. The Present Position of the Automatic Diesel-Electric Plant, E. J. Kates. *Mech. Eng.*, vol. 53, no. 7, July 1931, pp. 525-528, 2 figs.; see also *Power*, vol. 73, no. 25, June 23, 1931, pp. 990-993, 4 figs. Paper before Am. Soc. Mech. Engrs., previously indexed from Advance Paper, for mtg. June 23-26, 1931.

POWER PLANTS—COSTS. Report on Oil Engine Power Cost for 1930. *Am. Soc. Mech. Engrs.,—Advance Paper*, for mtg. June 23-26, 1931, 5 pp. Information covering 81 oil-engine generating plants, containing 253 engines, totaling 146,865 rated b.hp.

Electrical Engineering

The High Tension Conference. *Engineering*, vol. 131, no. 3413, June 12, 1931, p. 773, 2 figs. Sixth session of International Conference on Large High Tension Systems will take place from June 18 to 27, in Paris; reports on following subjects will be presented: study of behavior of transformer and other insulating oils; design and tests of oil circuit-breakers; parallel operation of power plants; investigation of surges; study of reactive power; grounding of neutrals; high-tension insulators and high-tension underground cables.

BIBLIOGRAPHY. A Bibliography of Bibliographies in Electrical Engineering 1918-1929, edited by K. Maynard. Providence, R. I., Special Libraries Assn., 1931, 156 pp., $1.50. List of references, without annotations, from 68 serials, arranged alphabetical by subject headings, giving number of items.

Electric Discharge

AIR. Berechnung der Anfangspannung zwischen kantigen Elektroden in Luft (Calculation of Initial Voltage Between Edged Electrodes in Air), W. Schilling. *Arbeiten aus dem Institut fuer elektrische Messkunde und Hochspannungstechnik der Technischen Hochschulp Braunschweig*, vol. 1, 1931, pp. 1-12, 15 figs. Field distribution; general discharge conditions and their application in calculation for various positions and edge angles.

MERCURY VAPOR. Electrical Discharges in Mercury Vapour and Their Control, H. de B. Knight. *Rugby Eng. Soc.—Proc.*, vol. 25, pt. 1, 1930-1931, pp. 23-62, 7 figs. General features which are of importance in connection with prevention of backfiring in mercury-arc power rectifiers, and operation of thyratron. Bibliography.

Electric Drive

BLOOMING MILLS. Algoma Steel Corporation Modernizes Rail Mill, A. F. Kenyon. *Blast Furnace and Steel Plant*, vol. 19, no. 6, June 1931, pp. 832-835, 4 figs. Previously indexed from Elec. News, Apr. 1, 1931.

ROLLING MILLS. The Twin-Motor Drive for Main Rolls, R. H. Wright and H. E. Stokes. *Rolling Mill Jl.*, vol. 5, no. 6, June 1931, pp. 403-406, 4 figs. Development and advantages of this type of drive. Before Assn. Iron and Steel Elec. Engrs.

Electric Light

General and Supplementary Lighting Components, M. Luckiesh. *Elec. World*, vol. 98, no. 2, July 11, 1931, p. 74. Notwithstanding many factors involved in lighting for seeing, means available to lighting specialist for improving seeing are relatively few compared with those available to seeing specialist; among these, quantity of light, or foot-candles, is by far most effective for universal application.

ULTRA-VIOLET. Diffusely Transmitting Media for Ultraviolet Radiation, M. Luckiesh. *Elec. World*, vol. 97, no. 26, June 27, 1931, pp. 1232-1233. Results of measurements of diffuse transmission for light and for ultraviolet radiation; measurements of ultra-violet transmission were made by use of blue fluorescing attachment for Macbeth illuminometer, using sunlight "Mazda" lamp (S-1) as source of ultra-violet radiation.

Electric Manufacturing Plants

TIME-STUDY. Use of Formulas and Charts for Rate-Setting, G. J. Stegemerten. *Factory and Indus. Mgmt.*, vol. 82, no. 1, July 1931, pp. 52-56, 4 figs. Compilation of set of time tables by Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

Electric Power

Electrical Home Service, E. E. Hoadley. *Elec. Rev.*, vol. 108, no. 2795, June 19, 1931, p. 1028. Practical comment and experience of consumers point of view on cost of service; flat irons; heating; cooking; water heating; future; all-electric homes. Before Inc. Mun. Elec. Assn.

Electrochemistry

A Method for Determining the Change in Transference Number of a Salt with Change in Concentration; a Modification of the Moving Boundary Method, E. R. Smith. *U. S. Bur. Standards—Jl. Research*, vol. 6, no. 6, June 1931, pp. 917-926, 5 figs. Junctions between solutions of same salt at different concentrations are formed and volumes through which junctions move during passage of known amounts of electricity are measured; method was tested for solutions of lithium, sodium, and potassium chloride.

Electrolytic Oxygen

MANUFACTURE. Markets for Gases Electrolyzed with Off-Peak Power, P. McMichael. *Elec. World*, vol. 97, no. 25, June 20, 1931, pp. 1182-1185, 3 figs. Outlets for oxygen well established; new hydrogen markets make electrolysis of water economically feasible; cell plant in conjunction with generating station to utilize off-peak power.

Engineering

INDUSTRIAL RELATIONSHIP. Coordinating Engineering with other Company Activities, L. E. Jermy. *Machine Design*, vol. 3, no. 6, June 1931, pp. 27-29. Procedure followed by eight companies using committees and conferences to broaden scope of activities of engineering departments.

INFLUENCE ON CIVILIZATION. Technology and Material Progress, W. R. Whitney. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 403-405. Paper before Am. Philosophical Soc., previously indexed from Science, May 8, 1931.

Engineering Education

Education for the Engineering Industry. *Nature (Lond.)*, vol. 127, no. 3215, June 13, 1931, pp. 881-886. Review of report of Committee appointed by President of Board of Education to inquire into technical education for engineering industry.

Engineering Ethics

A New Code of Ethics Needed. *Eng. News-Rec.*, vol. 106, no. 26, June 25, 1931, pp. 1036-1037. Editorial on necessity of revising engineering code of ethics, in such way that advertising and competition be recognized and proper limits set upon them; fees and compensation may also need to come up for consideration.

Furnaces

ANNEALING. The Annealing of Metal Strip in the Continuously-operated Electric Furnace. *Metal Industry (Lond.)*, vol. 38, no. 26, June 26, 1931, pp. 641-643, 4 figs. In addition to electrically heated muffle furnaces, specially designed types of furnace have been put on market, and in particular, so-called "pull-through" furnaces; as against short type, horizontal pull-through furnaces, where wages constitute higher portion of total operating costs, continuously working strip annealing plants with pickling trough, washing machine and drying furnace, are capable of meeting most exacting demands.

ENAMELING. Economic Operation of Electric Enameling Furnace, A. M. Young. *Elec. World*, vol. 97, no. 25, June 20, 1931, pp. 1168-1170, 1 fig. Difference of nearly 13 per cent in net rate for furnace energy from one month to next was disclosed by recent study of electric enameling operation in plant of Chicago Hardware Foundry Co. at North Chicago, Ill.; difference was caused by varying incidences of furnace demand on total plant demand; charts showing effects of furnace load on customer's demand.

INDUCTION. Tonnage Melting by Coreless Induction—IV, E. F. Northrup. *Fuels and*

Furnaces, vol. 9, no. 7, July 1931, pp. 833-838, 3 figs. Stirring of metal and its control and power density of large and small furnaces.

REFRACTORY MATERIALS. Refractory Materials for Electric Furnaces—III, A. B. Searle. *Metal Industry (Lond.)*, vol. 38, no. 23, June 5, 1931, pp. 569-571. Nickel and its alloys, including nickel-chromium alloys and nickel-silver; fact that nickel has melting point of 1,452 deg. cent. makes it necessary to employ, as materials for lining furnaces, those of greater refractoriness than ones used for copper and lead and their alloys.

Refractory Materials for the Induction Furnace, J. H. Chesters and W. J. Rees. *Iron and Steel Industry*, vol. 4, no. 10, July 1931, pp. 347-348. Paper before Iron and Steel Inst., previously indexed from Engineering June 12 and 26, 1931.

STEEL MAKING. Use of Sillimanite as Material for Furnace Covers, M. F. Sommer. *Blast Furnace and Steel Plant*, vol. 19, no. 6, June 1931, pp. 861-864, 1 fig. Tests indicate that sillimanite is much more expensive than silica, and durability under most favorable conditions is about same; no evidence was forthcoming which would lead to belief that through improvements in process of manufacture of either sillimanite bricks or of cover rammed up with sillimanite clay, increase in durability might be attained which would even approximately correspond to price ratio.

Generators

PARALLEL OPERATION. Re-exciting Loaded Alternators in Parallel with Others, D. D. Higgins and E. Wild. *Power*, vol. 73, no. 26, June 30, 1931, pp. 1041-1042. In order to establish reasonably safe operating procedure for such emergencies and one that will reestablish normal conditions just as soon as possible, authors have collected data on experiences and statements for various sources and have determined, by tests, behavior of large units under these abnormal conditions. Before Am. Inst. Elec. Engrs.

REGULATION. Generator Voltage Regulated by Corona Tube, H. W. Dodge and C. H. Willis. *Elec. World*, vol. 98, no. 1, July 4, 1931, pp. 25-26, 4 figs. Characteristics of corona discharge tube make its critical voltage suitable for constant element in regulator; fact that it regulates to constant peak voltage rather than constant effective voltage is not serious disadvantage, for variation of wave form with load is not appreciable and there will therefore be constant form factor. Before Am. Inst. Elec. Engrs.

SYNCHRONIZING. Correct Generator Synchronizing Insured by Auxiliary Control, J. Auchincloss. *Elec. World*, vol. 97, no. 26, June 27, 1931, p. 1214, 1 fig. Auxiliary switches on generator breaker control prevent faulty closing; wiring diagram.

Limitations in Synchronizing, H. S. Baker. *Hydro-Elec. Power Commission of Ont.—Bul.*, vol. 18, no. 6, June 1931, pp. 208-220, 28 figs. In hand synchronizing, limitations of speed difference and phase differences at moment of closure are learned in very crude manner; with automatic synchronizing it is possible to set above speed difference and phase difference limitations to known values; object of paper is to determine in rational manner values of these limitations in order to be able to make necessary adjustments to automatic synchronizing devices.

Hoover Dam

CONSTRUCTION POWER LINE. Rushing the Power Line to Hoover Dam Site, R. H. Halpenny. *Eng. News-Rec.*, vol. 106, no. 26, June 25, 1931, pp. 1054-1057, 5 figs. Rugged desert country crossed in 225 days by 225 mi. 132 kv. transmission line from San Bernardino, Cal. to serve Hoover Dam construction activities digging 7 ft. holes for tower bases; four erectors and two helpers fabricated each 52-ft. tower piece by piece from ground up; stringing three conductors at same time.

Hydroelectric Plants

DROUGHT EFFECT. Drought of 1930 Shifts Power Load to Steam Stations, G. T. Bogard. *Southern Power Jl.*, vol. 49, no. 6, June 1931, pp. 34-38, 4 figs. Following three articles outline power generation difficulties experienced in south during 1930: Unparalleled Water Deficiency Seriously Affected Even Steam Stations, G. T. Bogard; High Steam Electric Capacity Solves Drouth Problems in West Virginia, G. Ellis; Excellent Maintenance Stood Virginia System in Good Stead, M. Cary; principal generating stations as of January 1, 1931, Kentucky Utilities Company and Appalachian Electric Power Company; records of river flow and hydro power output for 1928, 1929 and 1930.

MAINTENANCE AND REPAIR. Organizing for Plant Operation and Maintenance, A. S. Robertson. *Hydro-Elec. Power Commission of Ontario—Bul.*, vol. 18, no. 6, June 1931, pp. 190-200, 5 figs. Value of service shop; organization chart and proposed maintenance schedule and actual record in days for Queenston generating station; duties of operating staff; preparing maintenance schedules; reducing time and costs; example of detailed job for rewinding a large generator; assembly of several individual job schedule sheets covering major repair on large unit.

NEW BRUNSWICK. The Economics of Power Plant Design, H. G. Acres. *Contract Rec.*, vol. 45, no. 24, June 17, 1931, pp. 731-734, 8 figs. Brief description of plant, for Edmundston, N. B., with 1,050-hp., high-speed, propeller-type, vertical turbine, direct-connected to 1,000-kva., 3-phase, 60-cycle, 2,300-volt, 240-r. p. m. generator, with direct-connected exciter and Kingsburgh thrust-bearing.

PUMPED STORAGE. High-Head Pumped-Storage Hydro-Electric Plant. *Engineering*, vol. 132, no. 3417, July 10, 1931, p. 61, 1 fig. New Plant at Sillre, town on River Indal, 220 mi. north of Stockholm; scheme is to employ power from existing plants, which is now suffered to escape in slack periods, to generate current which is to be transmitted to plant at Sillre, there to pump water up into storage reservoir.

Insulators

MANUFACTURE. The Manufacture of Porcelain Insulators. *Engineer*, vol. 151, no. 3935, June 12, 1931, pp. 658-659, 5 figs. Plants of Bullers, Ltd., at Milton and Tipton, England; manufacturing process and equipment; research work carried out by Company; every type of insulator used in electrical industry for telegraph and telephone work and for power work is made in Company's factories, including cap and pin-type insulator strings used for 132-kv. grid lines.

Lighting

COLOR. Work-World Environments, M. Luckiesh. *Mech. Eng.*, vol. 53, no. 7, July 1931, pp. 514-518. Light and color fundamentally desirable and powerful influences upon happiness; color schemes for factory interiors and machinery; economic value of pleasant environments for workers.

INDUSTRIAL. Good Lighting is a Good Investment, H. Chase. *Iron Age*, vol. 128, no. 2, July 9, 1931, pp. 84-87, 3 figs. Uniform illumination without glare or deep shadows is unquestioned aid in economical production work; examples show how properly designed system may result in enough saving to pay for equipment in less than year.

MOTOR BUS. Lighting Motor Buses and Coaches. *Ry. Gaz.*, vol. 55, no. 1, July 3, 1931, pp. 19-20, 4 figs. Details of dynamo designed to give 12 volts, 25 amp. from 1,500 to 4,000 r. p. m.; drivers switchboard; lighting controls for switchboard and interior lighting.

SHIP. Pivoted Ship Sidelight. *Engineering*, vol. 132, no. 3416, July 3, 1931, p. 28, 3 figs. New light introduced by J. Stone and Co., Deptford; sidelight is called stirrup light, as control is entirely effected by single stirrup-shaped handle.

STREET. Street Lighting and Traffic Accidents, K. M. Reid. *Elec. World*, vol. 97, no. 25, June 20, 1931, pp. 1186-1188, 3 figs. Analysis of Police department records of Cleveland, showed that traffic accidents in winter dusk exceeded midsummer's frequency; what good lighting system has accomplished; relation of lighting to fatal traffic accidents; fatalities on State roads in relation to lighting; Indiana highway fatalities. Before Am. Soc. Mun. Engrs.

UNITS. The Waidner-Burgess Standard of Light, H. T. Wensel, W. F. Roeser, L. E. Barbrow and F. R. Caldwell. *U. S. Bur. Standards—Jl. Research*, vol. 6, no. 6, June 1931, pp. 1103-1117, 4 figs. partly on supp. plate. Source of light sufficiently reproducible to serve as fundamental photometric reference standard has been obtained by carrying out in original suggestion of Waidner and Burgess to immerse hollow inclosure in bath of molten platinum and to make observation during period of freezing.

Lamps

Characteristics of Electric Lamps as Modified by Modern Methods of Manufacture, L. E. Buckell. *Machy. Market*, no. 1599, June 26, 1931, pp. 23-24. Early developments; introduction of metal filaments; gas-filled lamps; standardization; manufacturing methods; effects of small variations; uniformity of life; spiral filaments. Before Assn. Supervising Elec. Engrs.

Measuring Instruments

New Developments in Electrical Measuring and Auxiliary Testing Devices. *Nat. Elec. Light Assn.—Pub.*, no. 128, June 1931, 48 pp., 148 figs. Information concerning such devices and improvements which have been made available during year.

Meters

Direct Current Meters, S. B. Warder. *Elecn.*, vol. 106, no. 2769, June 26, 1931, pp. 941-942, 4 figs. Characteristics of ampere-hour and watt-hour meters.

SPECIFICATIONS. Summary of Public Utility Commission Rules and Regulations for Electricity Meters. *Nat. Elec. Light Assn.—Pub.*, no. 132, May 1931, 20 pp.

WATT-HOUR. Watt-Hour Meters, E. Fawssett. *Elec. Rev.*, vol. 108, no. 2795, June 19, 1931, pp. 1043-1044. Latest induction watt-hour meters are compared with those of few years ago, while there is no outstanding change to record, there has been distinct progress in detail and in performance.

Les compteurs Electriques a mercure (Mercury Watt Hour Meters), V. Neveux. *Industrie Electrique*, vol. 40, no. 935, June 10, 1931, pp. 253-261, 13 figs. Meters using mercury as low-friction material for pivoting; type of Ferranti Co., Chamberlain, Hookham, Compagnie pour la fabrication des compteurs, and Sangamo Electric Co.; applications.

Summation Meters and Some New Applications—1, C. W. Olliver. *Power Engr.*, vol. 26, no. 304, July 1931, pp. 270-273, 5 figs. Review of some modern summation equipment, with particular reference to their application to power station and other mechanical requirements.

Motor-Generators

Sur la régulation directe et les difficultés qu'entraine son etude (Direct Regulation and Difficulties in Its Analysis), Barbillion. *Revue de L'Industrie Minerale*, no. 250, May 15, 1931, pp. 171-185, 13 figs. In more general previous study (see Engineering Index 1930, p. 624), it was assumed that proportionality existed between terminal voltage and variations in angular speed; in present article, application in cases of temporary disturbances is mathematically analyzed and some new approximately exact methods of calculation are given.

Motor Trucks

ELECTRIC. Electric Trucks. *Nat. Elec. Light Assn.—Report*, no. 138, June 1931, 12 pp., 10 figs. Degree of electric truck use by electric utilities; application to transportation work; successful truck designs and battery combinations; data and opinions gathered from operating companies.

Motors

BRAKING. Brakes for Motors and Their Loads, H. M. French. *Power*, vol. 73, no. 26, June 30, 1931, pp. 1024-1026, 5 figs. Large amount of data available on starting motors and running them to suit particular application; lack of braking information; means of retarding, stopping and holding motors under various conditions of operation.

INDUCTION—DESIGN. Theorie van den dubbel gekoppelden lek, in het bijzonder bij draaistroom-kortsluitankermotoren (Theory of Double Coupled Leak with Special Reference to Three-Phase Squirrel Cage Induction Motors), M. Van Der Veen. *Polytechnisch Weekblad*, vol. 25, nos. 20 and 21, May 14, 1931, pp. 313-316, and May 21, pp. 329-334, 15 figs. Theoretical mathematical analysis. Bibliography.

LAMINATIONS. Production of Motor Laminations, R. L. Payne. *Metal Stampings*, vol. 4, no. 6, June 1931, pp. 481-486, 9 figs. Four different methods of preparing silicon steel in sheet form for production of motor laminations and equipment used for their production; scrap economy in ultimate production of laminations lies in method of preparing sheets.

Paper Mills

POWER FACTOR. Correcting Power Factor While Grinding Wood Pulp, W. P. Lyman. *Elec. World*, vol. 97, no. 25, June 20, 1931, p. 1189, 1 fig. By applying synchronous machines to motorization of dual-drive pulper equipment, Bogalusa Paper Co. of Bogalusa, La., was able to take advantage of power-factor clauses in purchased energy contracts and secure satisfactory operating performance.

Permalloy

Researches on the Rotation of Permalloy and Soft Iron by Magnetization and the Nature of the the Elementary Magnet, S. J. Barnett. *Am. Academy Arts and Sciences—Proc.*, vol. 66, no. 8, June 1931, 348 pp., 46 figs.

Photoelectric Cells

Photo Cells and Thyratrons, L. J. Davies. *Elecn.*, vol. 106, no. 2769, June 26, 1931, pp. 936-938, 8 figs. Growing importance of vacuum devices; elements of cell; properties of thyratrons.

Power Factor

An Elementary Discussion of Power Factor, J. Leech-Porter. *Can. Min. Jl.*, vol. 52, no. 23, June 1931, pp. 584-587, 3 figs. Preliminary contribution to question of power factor correction; principles of power factor, which are not very clear to men outside those who have specialized in electrical engineering, in simple and direct way.

Power Industry

Public Interest Demands Utility Merchandising. *Elec. World*, vol. 97, no. 25, June 20, 1931, pp. 1180-1181, 4 figs. Oregon utilities justify merchandising on grounds that consumers are entitled to maximum usage at minimum rates and furnish evidence proving that only through their activities has been made possible; graphs showing average annual use of electricity per domestic customers, average rate per domestic kw-hr., average annual kw-hr. use per domestic customer and decrease in average rate per domestic kw-hr.

Power Plants

STEAM-ELECTRIC. Foreign Developments. *Nat. Elec. Light Assn.—Pub.*, no. 131, May 1931, 38 pp., 53 figs. In general, trend of power-plant development is toward higher pressures and temperatures; American viewpoint of European situation is presented in composite statement of several engineers who attended World Power Conference, Berlin; peak-load problem; tendencies of modern German steam generation; trend of developments in central stations and equipments in England; Golpa-Zschornewitz plant of Elektrowerke Aktiengesellschaft; tests on Ruths accumulator plant in Charlottenburg power station. Bibliography.

Power Supply

NEW YORK CITY. The Power Behind New York—II. *Power Plant Eng.*, vol. 35, no. 13, July 1, 1931, pp. 702-707, 7 figs. Features of system operation; analysis and application of load curves; factors affecting system operation; determination of incremental rates; frequency and voltage regulation.

RURAL. A Report on Farm Electrification Research. *Committee on Relation Electricity to Agriculture—Bul.*, vol. 6, no. 1, June 1931, 79 pp. Progress of investigations of different types which have been conducted; analysis of agricultural development; major economic and production problems in which electricity may be involved; plan and program for continuation of research activities; investigations under way and proposed; work done and need for further investigations in that particular field.

Pumping

PETROLEUM PIPE LINES. Electricity in the Transportation of Oil, G. R. Prout. *Oil and Gas Jl.*, vol. 30, no. 2 to 4, June 4, 1931, (supp.) pp. T99 and T101, 7 figs. Review of reasons for tendency towards use of electric motors for pipe line pumping; gathering line and trunk line work; advantages of automatic operation; Diesel electric pumping stations; 160,000 hp. in motor capacity is now installed in oil pipe line stations in central and southwest United States.

Remote Control for Electric Stations, L. G. E. Bignell. *Oil and Gas Jl.* vol. 30, no. 2 to 4, June 4, 1931, (supp.) pp. T49-T50, 1 fig. Outline of control system devised by Westinghouse Electric & Manufacturing Co.; one station equipped in Oklahoma.

Motor Heat Controlled in New Sinclair Pump Station, J. C. Albright. *Oil Weekly*, vol. 62, no. 2, June 26, 1931, pp. 25-26, 4 figs. Oklahoma City-Coffeyville line booster stations are all alike in design and equipment, with two Byron Jackson three-stage oil line pumps, capacity 60,000 bbl. oil daily at 3,550 r. p. m.; each pump connected by Fast's self-aligning coupling to General Electric Type FT-559-AY form EL2,200-volt three-phase 60 cycle induction motor, delivering 500 hp.; normal operating temperature 104 deg. fahr.; provisions for air circulation and hot air disposal.

Radio

AIRPLANES. Some Considerations Affecting Design of Aircraft Wireless Equipment, J. A. McDonald. *Roy. Air Force Quarterly*, vol. 2, no. 2, Apr. 1931, pp. 258-269, 4 figs. on supp. plates. Reliability and type of apparatus for signaling between aircraft in flight and between aircraft and ground stations.

Temperature Rating of Engine Driven Aircraft Radio Generators, C. B. Mirick and H. Wilkie. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1175-1181, 11 figs. Previously described methods of temperature measurement and computation are applied to engine driven aircraft radio generators in flight; observed and computed heating curves are shown from which emission constant for this type of machine has been derived.

AMPLIFIERS. High Audio Power From Relatively Small Tubes, L. E. Barton. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1131-1149, 11 figs. Method by which audio outputs 5 to 10 times usual output of tube of given size may be obtained with same plate voltage, lower average plate dissipation, and no serious effects on tube; results are obtained by using in such manner that advantage is taken of essential features of class "B" amplifier.

Note on Radio Frequency Transformer Coupled Circuit Theory, J. R. Nelson. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1233-1241, 4 figs. Equations considering effects of output and distributed capacities and primary resistance are developed for radio-frequency transformer-coupled amplifiers using either tuned or untuned primary; these equations are transformed to such form that they may be compared with well-known equations derived for untuned primary neglecting output and distributed capacities; equations for untuned primary are verified experimentally.

AMPLIFIERS—COUPLING. Maximum Amplification in Capacity-coupled Circuits, W. van B. Roberts. *Electronics*, vol. 3, no. 1, July 1931, pp. 20 and 42, 2 figs. In analysis given only two approximations are introduced and neither of these is believed to be capable of making appreciable difference in any ordinary circuit.

ANTENNAS, SHORT WAVE. Theoretical and Practical Aspects of Directional Transmitting System, E. J. Sterba. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1184-1215, 19 figs. More important principles involved in development of directional transmitting antennas at present employed in Bell system short-wave facilities; theoretical performance of directive arrays is presented by means of various curves which have been obtained by integrations based upon Poynting's theorem; various practical problems in development including antenna tuning procedure, transmission line adjustments, and sleet melting facilities.

CIRCUITS—TUNING. Tuning by Permeability Variation, R. H. Langley. *Electronics*, vol. 3, no. 1, July 1931, pp. 8-10, 2 figs. Results of W. J. Polydorff studies and experiments by which is attained that variable air condensers are replaced by iron cores inserted gradually into radio frequency transformers; curve showing amplification and selectivity of screen-grid tube with iron core transformer; simple analysis is given.

COILS—DESIGN. Supplementary Note to the "Study of the High-Frequency Resistance of Single-Layer Coils," A. J. Palermo and F. W. Grover. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1278-1280. Since publication of above paper in Dec. 1930 number, indexed in Engineering Index 1930, p. 1415, attention of authors has been called to two articles on a-c. resistance of solenoidal coils by S. Butterworth, which were overlooked in preparation of paper; tabulated results show that for coils measured, Butterworth's formula 30 gives best agreement with measured values in all except few cases.

DETECTORS. High Level Automatic or Self-Bias Detection, J. R. Nelson. *Electronics*, vol. 3, no. 1, July 1931, pp. 14-15, 3 figs. Circuit used for experimental determination of self-bias detection characteristics; calculation of rectified output; dynamic characteristics of typical self-bias detector; rectification curves of 27 detectors.

FREQUENCY—MEASUREMENT. Frequency Measurement in the British Post Office, F. E. Nancarrow. *Post Office Elec. Engrs.—Jl.*, vol. 24, pt. 2, July 1931, pp. 155-159, 4 figs. In radio department of British Post Office, all frequencies are measured by reference to harmonic frequencies of tuning-fork maintained in Radio laboratories at Dollis Hill, Lond.; this fork can be regarded as Post Office standard of frequency; fork and temperature control; pressure effect.

MEASURING INSTRUMENTS. Thermojunctions at High Radio-frequencies, F. M. Colebrook. *Experimental Wireless*, vol. 8, no. 94, July 1931, pp. 356-361, 5 figs. Object of investigation was to obtain information about frequency variation of thermo-junction milliammeters; tube rectifier milliammeters was specially designed for purpose of inter-comparison of thermo-junctions investigated and vacuum tube instrument.

OSCILLATORS, PIEZOELECTRIC. Performance of Piezo-Oscillators and the Influence of the Decrement of Quartz on the Frequency Oscillations, M. Boella. *Inst. Radio Eng. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1252-1273, 21 figs. Performance of piezo oscillators of usual Pierce circuits is treated, on basis of resonance curves of quartz and with help of vector diagrams; influence of decrement of quartz resonator on oscillation frequency is examined; study has led to arrangement which permits quartz to oscillate in proximity to its frequency of resonance and to reduce thereby influence of decrement on frequency to about 1/10 of that usually found.

TRANSMISSION. Notes on Radio Transmission, C. N. Anderson. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1150-1165, 16 figs. Considerable data on radio transmission have been obtained past few years in connection with establishment and operation of various radio-telephone services by Bell System; purpose of notes is to present certain aspects of some of these data which may be of interest in development of general physical picture of radio transmission and in indicating effects of disturbances accompanying storms in earth's magnetic field.

TUNING. Tuning by Permeability Variation, R. H. Langley. *Electronics*, vol. 3, no. 1, July 1931, pp. 8-10, 2 figs. Results of W. J. Polydorff studies and experiments by which is attained that variable air condensers are replaced by iron cores inserted gradually into radio frequency transformers; curve showing amplification and selectivity of screen-grid tube with iron core transformer; simple analysis is given.

Railroad

AUTOMATIC BLOCK SIGNALS. Committee VIII—Alternating Current Automatic Block Signaling, W. F. Follett. *Am. Ry. Assn.—Proc.* (*Signal Sec.*), vol. 28, no. 3, June 1931, pp. 487-490. Specifications covering made ground apparatus for lighting arresters; and oil-immersed self-cooled line transformers.

Committee IV—Direct Current Automatic Block Signaling, E. N. Fox. *Am. Ry. Assn.—Proc.* (*Signal Sec.*), vol. 28, no. 3, June 1931, pp. 490-500. Condensation of moisture and formation of frost on signal apparatus; direct current track circuit test record; plug type rail bonds and track circuit connectors; rail bond; plug type; track circuit connector; relay contact post designation plate.

INTERLOCKING SIGNALS. Committee II—Interlocking. *Am. Ry. Assn.—Proc.* (*Signal Sec.*), vol. 28, no. 3, June 1931, pp. 501-506. Car retarder system; electric motor switch operating mechanism; centralized traffic control system; centralized traffic control machine; electric look; time release; interlocking lever circuit controller.

ELECTRIC CONTROL SWITCHES. The Sheremeteff Electro-Gravity Point Mechanism. *Ry. Engr.*, vol. 52, no. 617, June 1931, pp. 214-215, 5 figs. partly on p. 224. Details of system in use on London and North Eastern, whereby wheels of passing train provide necessary energy for operating pair of points; wiring diagram of operating mechanism.

ITALY. The Bologna-Florence Direttissima Railway and the Great Apennin Tunnel. *Engineer*, vol. 151, no. 3936, June 19, 1931, pp. 676-680, 12 figs. Route has length of 97 km. with double track; maximum gradient is 1 in 83; stations are capable of accommodating trains 500 m. long; longest tunnels are Great Apennine, 18,510 m., Monte Adone, 7,135 m., and Pian di Setta, 3,045 m. long; longest viaduct is at Vado, carried on 14 arches, each of 20 m. span; ventilation and methods of driving tunnels; line will be electrified on three-phase system at 3,700 volts and 16⅔ cycles, current being supplied from converter station at San Viola, Bologna.

ELECTRIFICATION — LACKAWANNA. Lackawanna Railroad. *N. Y. Railroad Club—Off. Proc.*, vol. 41, no. 7, May 1931, pp. 9625-9660, 18 figs. Symposium of papers: Lackawanna Suburban Electrification in New Jersey, G. J. Ray; High Spots of Electrification on Lackawanna R. R., E. L. Moreland; Informative and Interesting Description of Sub-Stations and Construction of Catenary System, J. S. Thorp; My Experience with Commuters, J. J. Pierce; Multiple-Unit Cars, Three-Power Locomotives and Training of Employes for Delaware, Lackawanna and Western Railroad Electrification, E. E. Root.

SIGNALS AND SIGNALING. Committee X—Signaling Practice, W. M. Post. *Am.*

Ry. Assn.—Proc. (*Signal Sec.*), vol. 28, no. 8, June 1931, pp. 455-479. Automatic train control; locomotive cab signals; requisites for centralized traffic control system, automatic block signal system and interlocking system.

Rectifiers

JET WAVE. The Jet-Wave Rectifier; An Account of Its Constructional Development During the Years 1919-1929, no. 24, edited by J. Hartmann, Copenhagen, Danmarks Naturvidenskabelige Samfund I Kommission Hos G. E. C. Gad. *Vimmelskaftet* 32, 1931, 300 pp., figs., diagrs., 30 kr. General principles; jet; jet-wave; hydrodynamic circuit; magnet; auxiliary electrode; main electrode I; main electrode II; complete rectifier; rectifier plant; this research work has undertaken with view of developing high power rectifiers on basis of jet-wave principle; history of this principle and of its development before and after 1919 is given in appendix.

MERCURY-ARC. An Automatically-Controlled Rectifier on the London Underground Railway. *Engineer*, vol. 152, no. 3938, July 3, 1931, pp. 19-20, 7 figs. Rectifier installed by B. T. H. Co. in Hendon substation of London Electric Railway Co.; among special features, are: indestructible construction of anodes and anode enclosures, six-phase excitation, and accurate temperature control.

Mercury-arc Rectifiers, H. Rissik. *Elec. Rev.*, vol. 108, no. 2794, June 12, 1931, pp. 991-92, 6 figs. Recent developments in their application to heavy-duty work.

Refrigeration

Electric Refrigerators and Electric Refrigeration, C. H. Roe. *Ice and Refrig.*, vol. 80, no. 6, June 1931, pp. 473-474. Advent of electric refrigerators stimulated refrigeration industry; importance of information on performance and costs; standardization of household refrigerators. Before Nat. Electric Light Assn.

Resistance

GROUND. Guessing Ground Resistances Is a Risky Procedure, S. W. Borden. *Elec. World*, vol. 97, no. 25, June 20, 1931, p. 1172. Tests were made recently on steel tower line located where earth for some depth consists of sand and gravel; four tower legs, which form 15 ft. square, are buried directly in ground and each tower carries two three-phase, 66-kv. circuits; results of various measurements are given.

Substations

AUTOMATIC. Automatic Switching Equipment for Motor-generator Sets at the Campbell Works of the Youngstown Sheet & Tube Company, C. M. Myers and J. H. Graft. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 431-435, 7 figs. Central substation was erected in 1926; in selection of switching equipment for motor-generator sets; location for equipment; attendants available; importance of maintaining continuous power on all feeders; simplicity of equipment; justifiable cost are to be considered.

DESIGN. Meeting Space Limitations in Urban Substations. *Elec. World*, vol. 97, no. 26, June 27, 1931, pp. 1224-1229, 18 figs. Various basic principles of design affecting space allocation and number of detailed features of economical treatment in equipment placement by power companies in eastern New England are cited; table showing clearances according to operating voltages; used by Boston Edison Co. station engineering department.

Substation Expansion Typifies Economy of Designing for Future Requirements, A. Shipek *Elec. West*, vol. 66, no. 7, June 1, 1931, pp. 610-611, 3 figs. Design features of terminal substations of Puget Sound Power and Light Co. Seattle, Wash.

Switchboards

SUPERVISORY CONTROL. Miniature Supervisory Control Gives Creditable Performance, R. M. Stanley, *Elec. World*, vol. 98, no. 1, July 4, 1931, pp. 22-25, 2 figs. With miniature switchboard operator is at all times closer to indicating instruments, control switches, etc., and can give better and closer supervision to operation of equipment, resulting in better voltage control, frequency control and division of load among generating units; there is great saving in time during regular operation and human error is largely eliminated. Before Am. Inst. Elec. Engrs.

Switchgear

Switchgear, H. Astbury. *Engineer*, vol. 151, no. 3936, June 19, 1931, p. 680. Discussion on rupturing capacity of extra-high-tension and low-tension switchgear to be installed on customers' premises. Before Instn. Elec. Engrs.

Telephone

AUTOMATIC. Common Control System, R. Taylor and C. E. Beale. *Post Office Elec. Engrs.—Jl.*, vol. 24, pt. 2, July 1931, pp. 125-131, 6 figs. In Common Control System, transitory functions are performed by detached groups of relays, each group being arranged to control number of switches; to switches themselves are fitted only relays that are required for full duration of call, plus one relay that serves to link up with common control group during setting up of call.

CONDENSERS. Telephone Condensers, R. E. W. Maddison and S. Chapman. *Elec. Communication*, vol. 10, no. 1, July 1931, pp. 39-44, 3 figs. Production and properties of paper condensers, no theories of dielectrics are included; electrodes; paper; materials; impregnating medium; process of manufacture; "Mansbridge" Condensers; electric properties; capacity; power losses; life tests.

RELAYS. Characteristics of Strowger Relays, K. W. Graybill. *Telephone Engr.*, vol. 35, no. 6, June 1931, pp. 30-31, 4 figs. Various methods used to determine mechanical adjustment values of horizontal relays together with reference tables governing these values.

TRANSOCEANIC. International Telephony, H. S. Osborne. *West. Soc. Engrs.—Jl.*, vol. 36, no. 3, June 1931, pp. 148-160, 9 figs. General description of apparatus and characteristics of its operation.

Testing Apparatus

HIGH TENSION. High-Voltage Testing Equipments, E. T. Norris and F. W. Taylor. *Instn. Elec. Engrs.,—Jl.*, vol. 69, no. 414, June 1931, pp. 44-694, 26 figs. State of art of high-voltage generation, to assist intending purchasers of high-voltage testing equipments in deciding upon best type of apparatus to install and in specifying most suitable technical characteristics, and to help owners and operators of existing equipments to appreciate possibilities and limitations of their apparatus and thereby make full and efficient use of it. Bibliography.

Transformers

TAP CHANGERS. Transformer Tap Changing on Load. *Engineer*, vol. 151, no. 3937, June 26, 1931, pp. 704-706, 13 figs. With view to meeting demand for step switches for pressure regulation on Load, Oerlikon Co. has utilized its experience gained in connection with traction gear, and has evolved various types of apparatus.

VAULTS. Typical Construction in Underground Transformer Installations, J. D. Pease. *South. Power Jl.*, vol. 49, no. 6, June 1931, pp. 57-58, 3 figs. Constructional features of three installations of commercial and industrial transformer stations in underground rooms.

Transmission

Is A-C. Power Transmission Doomed? C. W. Olliver. *Power Engr.*, vol. 26, no. 303, June 1931, pp. 210-211 and 229, 2 figs. A-C. power transmission was necessary evil, imposed by impossibility of static transformation; recent progress, by removing this obstacle, may well turn a-c. transmission lines into relics of past; series systems; field of application of d-c. generating system; advantages of d-c. long-distance transmission.

Transmission and Distribution

Transmission and Distribution, J. R. Beard and J. Hacking. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 414, June 1931, pp. 730-750. Brief account of present-day practise in regard to various component parts of transmission and distribution systems; subjects are dealt with under heads: overhead lines; cables; switchgear; transformers; protection and control. Bibliography.

Transmission Lines

CONSTRUCTION. Construction Methods in Erecting Hydro 220,000-v. Transmission Lines, G. R. Greer. *Elec. Canada*, vol. 8, no. 3, Mar. 1931, pp. 10-17, 8 figs. Construction experience and methods on line Gatineau-Toronto in Canada.

TOWERS. Transmission Tower Design for Maximum Lightning Protection, C. L. Fortescue. *Elec. Canada*, vol. 8, no. 3, Mar. 1931, pp. 18-23, and 32, 8 figs. Design analysis, curves showing effect of ground resistance with surge at tower for two and three ground wires; comparison of time-lag curves or sphere gaps and needle gaps; method of finding effective distance from ground wire to cloud; suggested arrangements when two ground wires are used; extrapolated average time-lag curves for needle gaps in air; time-lag curves of suspension insulators, with conductor positive.

Trolleys

TRACKLESS. The Trolley Bus as a Load Builder. *World Power*, vol. 15, no. 90, June 1931, pp. 465-469, 12 figs. Question of substituting trolley-bus or motor-bus service for street-car system; overwhelming economic advantages of trolley-bus service; analysis made of significance of street-car; load to electricity supply position in general and to municipal undertaking in particular.

Turbo-Generators

ROTORS. Turboalternator Rotors, W. R. Needham. *World Power*, vol. 15, no. 89, May 1931, pp. 375-376. General progress in rotor construction; influence of mechanical stresses on design.

U. S. INTERSTATE COMMERCE COMMISSION. Engineering in Its Relation to the Interstate Commerce Commission, F. McManamy. *Mech. Eng.*, vol. 53, no. 7, July 1931, pp. 503-509. Creation, organization, and duties of Commission; work of its various bureaus, including services of engineers in valuation, analysis of expenditures for equipment maintenance, and extensions; examination of specifications for locomotives, safety devices, etc.; determination of suitability of containers for transportation of explosives, etc. Before Am. Soc. Mech. Engrs.

Vacuum Tubes

RESEARCH. Electronic Tubes in the Laboratory. *Electronics*, vol. 3, no. 1, July 1931, pp. 24-25, 4 figs. Symposium of short notes by W. O. Watson, on Calibration of Grid Gain Controls; Glow-tubes Check Operating Voltage, by Gray Telephone Pay Station Co.; Progress in South Analysis and Measurement, F. Trendelenburg, of Siemens, Berlin; Graphic Noise Level Recorder, by Bell Telephone Laboratories.

Welding

BOILER MANUFACTURE. Boiler Manufacturers Discuss Welding at Annual Meeting. *Boiler Maker*, vol. 31, no. 6, June 1931, pp. 151-157. Application of fusion welding to construction of boilers and pressure vessels discussed at convention of American Boiler Manufacturers' Association; charts summarizing production of steel boilers from 1919 to 1930 inclusive; smoke prevention conference committee; cost accounting committee report; auxiliary equipment; work of feedwater studies committee; report of welding committee and discussion.

HOUSES, STEEL. An Arc-Welded Residence. *Gen. Bldg. Contactor*, vol. 2, no. 7, July 1931, pp. 33-36, 4 figs. Construction of two-story, six-room dwelling erected of arc-welded steel panels at Larchmont, N. Y.

PIPE LINES. Progress Made in Electric Arc Welding, C. M. Taylor. *Oil and Gas Jl.*, vol. 30, no. 2 to 4, June 4, 1931, (supp.) pp. T115-T116 and T118, 10 figs. Advantages of new welding process are explained by vice president of Lincoln Electric Co.; shielded arc produces welds of high tensile strength, ductility and resistive to corrosion; greater welding speed is obtained.

PRESSURE VESSELS. Fusion Welding and Its Use in Pressure Vessel Construction, W. D. Halsey. *Boiler Maker*, vol. 31, no. 5, May 1931, pp. 125-126. Because of recent rapid development in fusion welding, American Society of Mechanical Engineers' Boiler Code Committee has in course of preparation, code covering use in pressure vessel construction; attitude of insurer of such vessels towards process, and procedure to be followed in applying coverage for installations of such character.

SHIPBUILDING. Welded Machinery Foundations for Ships, G. H. Moore, Jr. *Welding Jl.*, vol. 28, no. 333, June 1931, pp. 172-175, 15 figs. Paper before Am. Welding Soc. previously indexed from their Journal, Apr. 1931.

Welds

STRESSES. The Distribution of Stresses in Welded and Riveted Connections, W. H vgaard. *Nat. Academy Sciences—Proc.*, vol. 17, no. 6, June 1931, pp. 351-359, 6 figs. Results of tests made at Massachusetts Institute of Technology; fundamentals of method. See reference to paper indexed in Engineering Index 1930, p. 1900, from issue of Nov. 15, 1930.

Industrial Notes

Carbon Brush Dimensions to be Simplified.—A meeting of the standing committee in charge of Simplified Practice Recommendation R56-28, Carbon Brushes and Brush Shunts, was held at the office of the National Carbon Company in Cleveland, Ohio, on July 28, 1931. Those present represented manufacturers of carbon brushes and brush shunts, motor and generator manufacturers, and users of motors and generators. The committee voted to reaffirm all items in the present recommendation with the exception of brush dimensions. In the opinion of the members, a further simplification of dimensions could be agreed upon by all parties concerned within the next few months. The committee therefore voted to hold in abeyance the publication of a revised recommendation until the new list, showing a smaller number of brush dimensions, had been approved by manufacturers of brushes, and of motors and generators. It is expected that this will be done within the next three months, and will result in largely reducing the number of stock items catalogued by all manufacturers.

The committee further voted to include in the revised recommendation certain additional definitions, together with a table showing the nomenclature recently adopted by the brush manufacturers to indicate the various standard types of shunt connections. It is also hoped that a further reduction can be made in the number of shunt lengths. Some of the manufacturers have already reduced the number of lengths from six to three. As soon as the necessary approval has been secured from the various associations interested, the final revision will be submitted to the division of simplified practice, which will then undertake to secure the written acceptance of the entire industry, in accordance with the regular procedure.

Pittsfield to Build Largest Transformers.—The largest transformers ever built at the Pittsfield works of the General Electric Company will be constructed for the Commonwealth Edison Company of Chicago and the Super Power Company of Illinois as part of an order for more than $1,000,000 worth of equipment. Delivery of the 20 transformers involved is expected early in 1932. So large are eight of the units that special drop-frame transformer cars must be built to ship them. The transformers will be used on both ends of a new 220,000-volt transmission line extending about 100 miles from Powerton to the Crawford Avenue station of the Commonwealth Edison Company at Chicago. For the receiving end, there will be required four 67,500-kva. power transformers and four 50,000-kva. regulating transformers. The power units, the heaviest, will weigh 491,000 pounds each, filled with oil.

Physically they will rival other big units made at the Pittsfield works in recent years. They will be 30 feet high overall, 27½ feet long and 19½ feet wide. In addition to these power units for the receiving station, there will be four regulating units, of 50,000-kva. output each, somewhat smaller in size and weighing 146,000 pounds each. At the sending end of the line there will be four 600,000-kva. units, weighing 406,000 pounds each, and eight 30,000-kva. regulating transformers weighing 75,000 pounds each.

Large Switch Order to Delta-Star.—The Pennsylvania Railroad Company has awarded the Delta-Star Electric Company, Chicago, a $150,000 contract for manual and motor operated disconnecting switches to be used on the railroad's extensive electrification project.

New Cap Type Connector.—The W. N. Matthews Corporation, St. Louis, announces the addition of cap type connectors to its line of solderless service connectors. Matthews connectors are now made in two styles, the new cap type and the nut type. The following advantages are claimed for the new connector: There are only two pieces to handle; the clamping lugs are made of bronze; hard drawn copper wire instead of soft drawn wire may be used. Bad connections are eliminated; it can be used much more economically for heavy loads where twisting large wires is difficult; radio interference due to twisted tap wires becoming loose is eliminated, because positive contact is assured and vibration will not cause loosening of the connector.

New Friction Tape.—The mechanical sales division of the B. F. Goodrich Company recently announced the development of a new friction tape especially designed for electrical use. The tape is similar to inner type patching material and practically vulcanizes in place after applied, making a solid covering for wire. The tape is listed by insurance underwriters and is approved for electrical purposes as taking the place of both insulating material and ordinary cloth tape, according to the manufacturer. The tape is so designed that it can be rolled lengthwise around electrical conductors, and is especially applicable to wiring where it is difficult to wrap the wire. It is made in ¾ inch and 1½ inch widths, packed in rolls.

Trade Literature

Wire Rope.—Catalog, 280 pp. Describes the complete line of Roebling wire rope and wire for all purposes. Wire tables are included. John A. Roebling's Sons Company, Trenton, N. J.

Panelboards.—Bulletin CA-505-A, supplement, 8 pp. Describes new Square D shallow type convertible safety panelboards with capacities up to and including 100 amperes, 250 volts. Square D Company, Detroit.

Speed Regulators.—Bulletins 1101, 1102. Describe ventilated and totally enclosed type speed regulators for use with constant torque and variable torque a-c. and d-c. fractional horsepower motors. Ward Leonard Electric Company, Mt. Vernon, N. Y.

Metal Enclosed Switchgear.—Circular 1915, 12 pp. Lists the installations of Westinghouse metal enclosed switchgear, includes photographs and descriptions. Circular 1899, 8 pp., describes this class of equipment in detail. Westinghouse Electric & Mfg. Company, East Pittsburgh.

"Frog Leg" Type Armature Windings.—Bulletin 2135, 4 pp. Describes this type of armature windings for multipolar, direct-current generators and motors. Such windings have been installed to date in over 500 units ranging in size from 50 kw. to 7,000 hp., totalling approximately 400,000 kw. Allis-Chalmers Manufacturing Company, Milwaukee.

Switchboards.—Bulletin 700, 90 pp. Includes specifications and design of Diamond "E" and Square D switchboards and panelboards. A detailed group of recommendations are outlined for dead front, live rear and dead front, dead rear switchboards and power panels. Diamond Electrical Manufacturing Co., 1318 E. 16th St., Los Angeles.

Insulators.—Catalog. Describes the complete line of Lapp insulators. It contains full data on electrical and mechanical characteristics, together with suggested applications. Insulator hardware is also covered. The catalog has an automatic index which enables the user to quickly find the product sought. A special section on distribution and farm lighting equipment is included. Lapp Insulator Company, Inc., LeRoy, N. Y.

NEWS section this month is replete with echoes of the recent A. I. E. E. Pacific Coast "vacation" convention. (*See pp. 832-5.*) Discussion on the technical papers presented is summarized also. (*See pp. 835-7.*)

THE electrical engineering profession suffered a distinct loss in the recent deaths of four of its noted members. (*See pp. 843-4.*)

THE widely heralded plan for stabilizing industry proposed by Gerard Swope (F'22) is presented in full in this issue. (*See pp. 816-9.*)

LETTERS received by the editor during the past month reveal increasing interest among readers especially in those articles dealing with the effects of engineering upon human relationships. (*See pp. 840-1.*)

LAST call is issued for the impending A. I. E. E. Kansas City meeting. (*See p. 834.*)

TESTS show that power-frequency corona is of no value in damping transmission-line surges. (*See pp. 798-801.*)

A NEW scheme of relaying with only two pilot wires instead of the usual four, materially reduces the cost of this type of protection. (*See pp. 824-6.*)

ENGINEERING FOUNDATION'S symposium, "Has Man Benefited by Engineering Progress," is continued this month by a protest against the indirect bonus system. (*See pp. 812-3.*)

SOME of the mysteries of mercury arc rectifiers are revealed in three articles by five engineers intimately connected with their development and application. (*See pp. 788-98.*)

A SERIES of tests involving all stages of the discharge casts further light upon the complex phenomena associated with the electric arc as used in welding. (*See pp. 827-9.*)

THOSE interested in electric motors and their applications are referred to two articles on special designs of synchronous motors (*see pp. 814-5 and 819-23*) and a third dealing with repulsion starting for capacitor motors (*see pp. 830-1*).

COMMUNICATION plays an important part in power system operation as is well demonstrated in a group of five articles outlining the fundamental requirements of power companies and describing the facilities in use on four typical systems. These represent the joint efforts of six power engineers and three communication experts of the Bell telephone system. (*See pp. 802-812.*)

Arc Welding in Building Construction

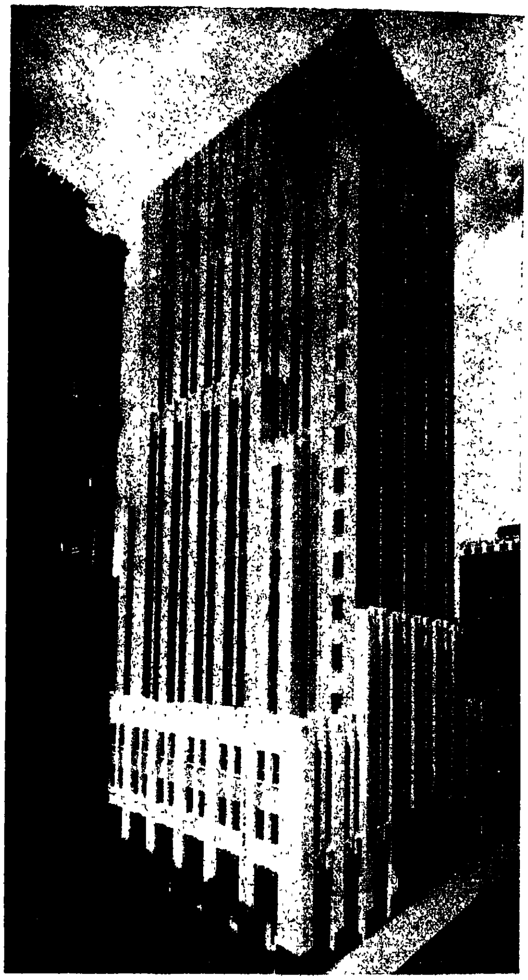
In this article are presented data obtained during the construction of the tallest building erected to date using the electric arc welding process. The outstanding advantages of this method of construction over the older method of riveting are (1) an almost complete absence of noise, and (2) the reduced steel tonnage required.

By
P. N. VINTHER Dallas Pwr. & Lt. Co., Dallas, Texas

WHILE electric arc welding has been used experimentally or commercially for more than half a century, its use in building construction extends back only three or four years. During these few years it has been applied successively to small, then to large and still larger projects until now because of its economy and quietness it is beginning to find favor in many quarters.

Because of its newness, most established building codes do not take cognizance of arc welding as a method of building construction. The first step in this direction was taken by the Pacific Coast Building Officials' Conference, which has included in its uniform building code the authority to use arc welding and has set forth therein the essential elements required by engineers and architects for working out designs of welded joints in steel beams and columns. A great many cities since have amended their codes to include arc welding; most of them have based their amendment on this Pacific Coast Building Officials' code. More and more municipalities are considering the advisability of adopting arc welding on steel construction as a means of obtaining quiet in the vicinities of hospitals, hotels, schools, and office buildings; wherever it has been used much satisfaction is evidenced.

The city of Dallas, principally through the efforts of local representatives of welding equipment manufacturers, legalized arc welding by ordinance in 1929. Accordingly the Dallas Power and Light Company, recognizing an opportunity to promote the use of electricity in a new field and to create a more livable condition for employees and neighbors during construction, concluded after thorough investigation to use welding in place of riveting in their new office building.



Nineteen-story arc-welded building of the Dallas (Tex.) Power & Light Company

This building is about 246 ft. high from basement floor to top of tank room roof, and is the tallest in the world to have employed this process to date. It consists of a nineteen-story main shaft (with basement) approximately 100 x 100 ft. at the base, and a 60 x 100-ft. connecting annex of two stories and basement. The main shaft is of modern design having an offset on the front at the sixth floor level and sym-

---

From "Electric Arc Welding in Building Construction," (No. 31M8) to be presented at the A. I. E. E. South West District meeting, Kansas City, M., Oct. 22-24, 1931.

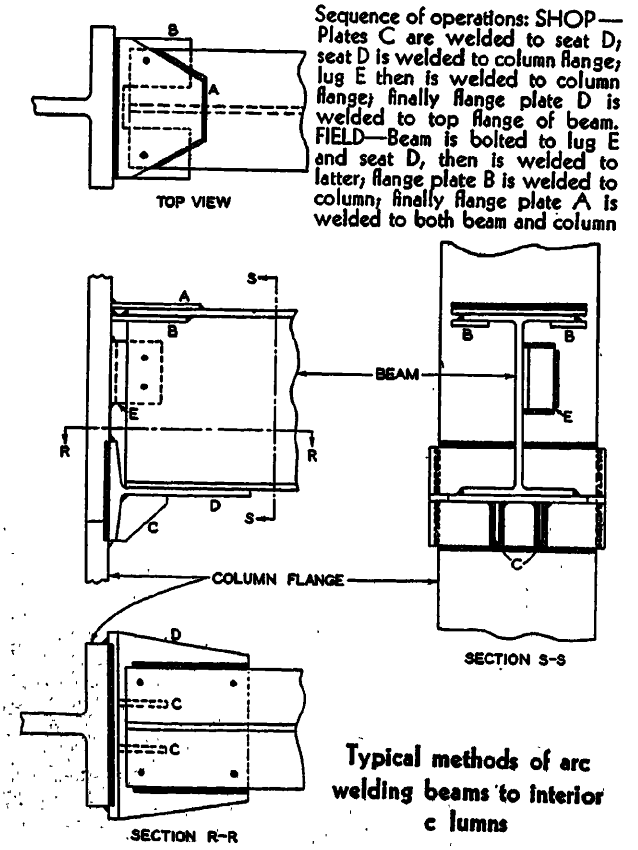
metrical setbacks on the two sides at the fourth and twelfth floor levels. The framing of this portion of the building consists of 25 H-section columns at the base spaced approximately 25 x 25 ft. and creating four 25-ft. bays each way. The width of the fourth floor setback is one-half a bay so that the outside columns from the fourth to the twelfth floors are carried on beams in the fourth floor. The twelfth floor offset is also half a bay, leaving the tower from the twelfth floor up two bays wide by the original four long, or approximately 50 x 100 ft. The sixth floor offset across the front is a minor one of only three or four feet and is carried by a second set of columns adjacent to the outside row, the outside row stopping with the offset and the adjacent row extending through to the top.

The second floor of the annex and the seventeenth floor of the main shaft are auditoriums. The second floor auditorium is spanned by five welded Warren trusses approximately 5 x 60 ft. The seventeenth floor auditorium, which really is two stories high, is spanned by three 12 x 50-ft. shop- and field-welded trusses, which not only support the ceiling of the seventeenth floor but carry on their bottom chords the nineteenth floor and on their top chords the roof, so that the nineteenth floor has the truss height for story height. The total weight of the steel is 1,170 tons for the main building and 45 tons for the annex. The steel was fireproofed with concrete, all of the slabs being of the pan and joist type poured on removable wooden forms. The building is provided with heavy wind bracing in both directions.

Since the success of welding depends upon the skill of the welders, the utmost care was used in selecting and training the mechanics employed. Each applicant was required to pass a rigid proficiency test before he was allowed to work. Only those welders whose specimens broke down at or above certain minimums set up for each type of weld were considered and then only provided their specimens showed uniformity in strength and appearance. While a good and uniform appearance in a weld does not of itself contribute directly to strength it is interesting to note that almost invariably the best looking work tests highest. For this reason a visual inspection is as effective as any other means yet devised, although certain mechanical and electrical methods now are being developed that no doubt some day will come into general use as an aid to the eye and sense.

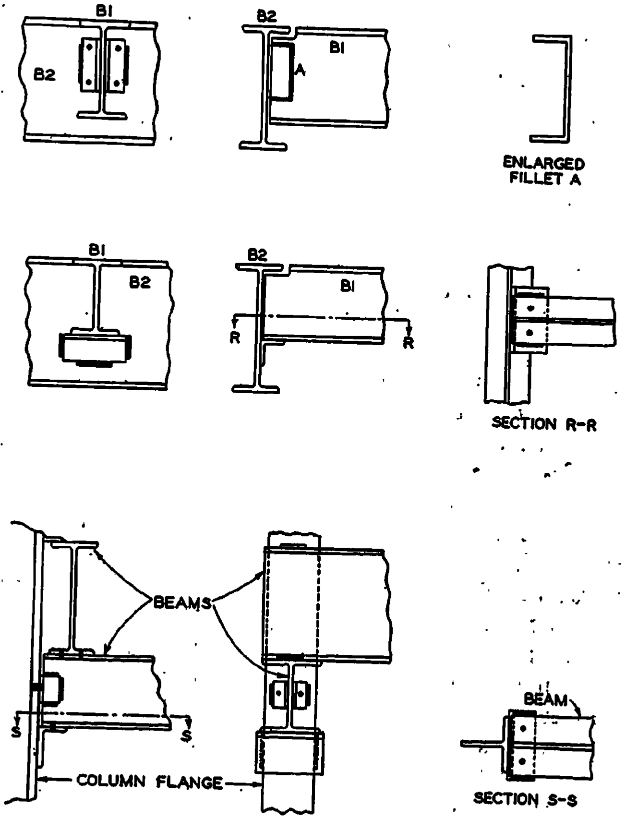
Welding equipment consisted of five 200-ampere portable motor-driven units of standard design, each used by a single mechanic.

The joining of the horizontal members or a horizontal



Sequence of operations: SHOP—Plates C are welded to seat D; seat D is welded to column flange; lug E then is welded to column flange; finally flange plate D is welded to top flange of beam. FIELD—Beam is bolted to lug E and seat D, then is welded to latter; flange plate B is welded to column; finally flange plate A is welded to both beam and column

Typical methods of arc welding beams to interior columns



Typical methods of arc welding small beams to larger beams and columns

Connecting angles are shop welded to small beams, and field welded to larger beams or columns. Shelf angles are shop welded to larger beams or columns member to a vertical member was accomplished by resting one member upon and field-welding it to a shelf shop-welded to the other. These shelves afforded not only a rest for members until welding could be completed, but also provided location for temporary construction bolts which, together with the customary cables and turnbuckles, were used in erection. Additional angles, I's and gussets then were added and the necessary amount of welding, measured in inches, was applied to provide the required strength. Care was exercised in the location and arrangement of these auxiliary pieces that as much of the welding as possible might be done at the shop and that overhead welding might be held to a minimum. Column splices were made by butting the ends together at the field and adding splice and filler plates, then welding to the required strength. Typical connection details are shown in the illustrations.

Most of the pertinent data collected during erection is given in the accompanying tabulation.

Arc-welding data for the Dallas Power & Light Company's nineteen-story building

Item	Description		Shop	Field
1.	Electrode bought	Lb	7,100	4,650
2.	Electrode melted (assumed 70%)	Lb	4,970	3,255
3.	Energy used	Kw-hr.	No record	9,460
4.	Total steel welded	Tons	1,215*	1,170*
5.	Welders' time	Man-hr.	3,140	1,768
6.	Total length of 3/8-in. fillets	In.	97,500	56,415
7.	Total length of 1/2-in. fillets	In.	25,400	17,842
8.	Total length of all fillets	In.	122,900	74,257
9.	Fillet per ton of steel	In.	101.2	63.5
10.	Fillet deposited per man per hour	In.	29.2	42.0
11.	Fillet deposited per man per 8-hr. day	Ft.	26.13	28.0
12.	Fillet deposited per lb. of electrode bought	In.	17.3	16.0
13.	Fillet deposited per lb. of electrode melted	In.	24.7	22.8
14.	Fillet deposited per kw-hr	In.	—	7.9
15.	Electrode melted per kw-hr	Lb.	—	0.34
16.	Energy required to melt 1 lb. electrode	Kw-hr.	—	2.90
17.	Welding man-hours per ton of steel	Man-hr.	2.58	1.51
18.	Electrode bought per ton of steel	Lb.	5.84	3.98
19.	Electrode melted per ton of steel	Lb.	4.08	2.78
20.	Electrode melted per hour per welder	Lb.	1.58	1.84
21.	Electrode melted per linear inch of fillet	Lb.	0.040	0.044
22.	Energy required per ton of steel	Kw-hr.	—	8.09

*Difference between shop and field tonnage due to 45 tons in a two-story wing not included in record.

Erection of the building was begun on July 18, 1930, and was completed September 3 of the same year. Field-welding operations were started on July 23, being completed September 11. In the completed building only two or three evidences remain to testify against the welding process and each of these could have been eliminated had the designers of the building possessed the experience that now is theirs.

Great progress in welding is being made. Many new problems are encountered on every job and are being worked out. The summation of the solutions of all these problems will constitute a goodly store of knowledge from which the architect and engineer may be able to design simply and practically and the contractor to fabricate economically. Even then prejudice in the minds of the non-progressive element will have to be overcome. Possibly new weights and shapes of members will have to be devised in order to reap most fully the benefits of the possibilities for reduced tonnage. Whatever are the obstacles in the path of the development in the art they all will be overcome with time. While at present it cannot be said that welding is due to supplant riveting in every kind of steel job, there is no doubt that the increasingly congested condition of commercial areas and the increasingly insistent demand on the part of the people therein for quiet will keep engineers, architects, and scientists busy.

Lumber Moisture Content Determined Electrically

THE OPERATION of determining accurately the amount of moisture present in lumber is reported to be greatly simplified by an electrical apparatus developed by C. G. Suits of the General Electric research laboratory, Schenectady, N. Y., and M. E. Dunlap of the United States Forest Products Laboratory at Madison, Wis.

The device utilizes simple tuned circuits involving two neon glow lamps. One of the neon lamps is

Portable electric lumber-moisture tester connected across a fixed condenser so adjusted that as the condenser successively builds up and discharges, this tube produces a characteristic red flash at the rate of about once per second. The other neon tube and its associated condenser are in series with the knife-edged electrodes on the specially treated wooden hammer. These electrodes, when driven into the grain of the lumber to be tested, complete an electrical circuit the characteristics of which depend upon the resistance of the wood between the two hammer electrodes. The rate at which this condenser builds up its charge depends upon the conductivity, and therefore upon the moisture content, of the wood under test. By means of a variable condenser this second tube circuit is adjusted so that the two tubes flash simultaneously, thus permitting the dial reading of the variable condenser to be calibrated to reveal the percentage of moisture in the lumber under test. Ear-phones may be substituted for the neon tubes where bright sunlight interferes with the visual effect of the tube flash.

Investigations indicate that with the exception of certain heavy imported woods, dependence may be placed upon the determination of moisture content as revealed by such a resistance test.

Solving the Mystery of Mercury Arc Rectifiers

By
ALBERT W. HULL
Non-member

HERBERT D. BROWN
Associate A. I. E. E.

Both of
General Electric Co.,
Schenectady, N. Y.

The three factors most important in mercury arc rectifiers are vapor pressure, arc-drop, and geometry of the anode housing. Investigations of such factors described in this article, have increased the capacity of rectifiers considerably and made it possible to eliminate several undesirable features of their operation.

EXPERIMENTAL research during the last three years has removed much of the mystery which shrouded the mercury arc rectifier, and made it a piece of standard electrical apparatus comparable to the motor and transformer. Much remains to be learned but these investigations have expanded greatly the range of current and voltage that can be handled by a rectifier and have indicated the path for still further progress.

The differences between the early rectifiers and the more modern type illustrated in Fig. 1 are mostly in the neighborhood of the anodes. One conspicuous change may be dismissed with a very brief statement, *viz.*, the change from mercury-cooled iron anodes supported by porcelain bushings, to graphite anodes with micalex bushings. The micalex seal is made from a mixture of mica and lead borate glass, fused and molded under high pressure, yielding a vacuum-tight seal of high mechanical and dielectric strength. This allows the clamped seal to be metal-metal instead of metal-porcelain, thus avoiding differential lateral expansion.

The normal operating requirements of a rectifier are very simple:

1. It must start easily, *i.e.*, it must begin rectifying whenever the a-c. crest voltage exceeds the d-c. line voltage by a small margin, of the order of 20 volts.

2. It must not arc back, *i.e.*, allow current to pass in the reverse direction.

3. The voltage drop between anode and cathode, when current is flowing, must be low enough to meet the efficiency requirements. The practical limits of voltage drop, which are approximately 20 volts minimum and 40 volts maximum, are generally satisfactory for line voltages of 500 or more, but are too high for 250-volt operation. The hot-cathode rectifier promises to fill this gap.

4. Voltage regulation will be required in the future. This is a circuit function rather than a rectifier function in the case of a simple rectifier, and can be accomplished by transformer compounding; but grid-controlled rectifiers of the type illustrated in Fig. 1, called thyratrons, can be made to give any desired regulation without compounding.

The arc-back requirement has received most attention up to the present, because the greatest electrical sin of today is interruption of service. When a rectifier arcs back it is a two-way conductor instead of one-way and hence constitutes a short circuit of the a-c. supply line as well as the d-c. line or network which it feeds. The harm done by such short circuits, assuming they are cleared by circuit breakers, is mainly interruption of service.

The gas evolution accompanying arc-back, if excessive, may delay resumption of service until the pumps can restore the necessary vacuum. Fast pumps and

---

From "Mercury Arc Rectifier Research," (N . 31-49) presented at the winter convention of the A. I. E. E., New York, N. Y., January 26-30, 1931.

well-degassed anodes have reduced this time to the order of one minute, and experiments now in progress are expected to reduce it to one second or less.

CONTROL OF MERCURY VAPOR PRESSURE

The most important single factor in mercury arc rectifier operation is the control of the mercury vapor pressure. This pressure depends on the temperature of the cooling water. The problem for investigation divides itself into two parts: (*a*) Assuming that the cooling-water temperature is uniform, what is the best temperature, and what are the permissible temperature limits? (*b*) If the water is not uniform, in what parts of the rectifier should the temperature be controlled?

The optimum temperature may be determined empirically by gradually increasing the load current at a given water temperature until a limiting temperature is reached, above which the rectifier will not operate at any load. Uniform temperature of the cooling water is maintained by rapid circulation. In this way a load-temperature curve is obtained, as shown in Fig. 2. The ordinates represent the maximum safe load for reliable short-time operation at each temperature. The important fact to be noted is that, while operation is possible at any temperature below a definite maximum, the load that can be carried is small at low temperatures and increases uniformly with temperature. The best operating temperature therefore is as near the maximum as can safely be maintained; and for a given load there is a definite operating range of temperature. For example, for the rectifier represented in Fig. 2, the operating range for a load of 1,500 amperes is between 42 and 60 deg. cent., as indicated by the shaded area. It is seen that there are two limitations to the range of reliable operation at a given voltage. One is high temperature, *i. e.*, high vapor pressure of mercury; the other is high current.

The maximum vapor pressure for a given operating voltage may be expected to follow closely the relation between vapor pressure and sparking potential; in fact, the only difference to be expected between arc-back potential and sparking potential is the change in the surface condition of the negative electrode, due to the presence in and just below the surface of gas molecules which have penetrated the surface in the form of positive ions. Such a composite surface is known to emit electrons more easily than a pure metal surface, and may be expected to allow a spark discharge at lower voltage. Hence the arc-back voltage should be very close to the sparking potential between electrodes of low electron work-function.

This conclusion appears to be justified by the results of a large number of tests made of sparking potentials. Typical results are shown in Fig. 3 which gives the sparking potential of an idle iron anode in a rectifier having 15-cm. diameter arms, with and without current to an adjacent anode. It is seen that the presence of ions due to current in the adjacent arm lowered the sparking potential by 50 per cent for the same vapor

Improving the Mercury Arc Rectifier

SOME of the problems most important to the successful construction of mercury arc rectifiers are discussed on these and the following nine pages. The first article, that by Hull and Brown, is a general treatment of the research problems which are being encountered in improving such rectifiers. Investigations are described of the three factors which the authors believe to be most fundamental; namely, vapor pressure, arc drop, and geometry of the anode housing. The second article, by Slepian and Ludwig, is concerned principally with the cause and occurrence of backfire in mercury-arc rectifiers, together with possible means for reducing the frequency of its occurrence. The authors point out that the random nature of backfire is not always appreciated, but that an understanding of this characteristic is essential to its elimination. The third article, by DeBlieux, is concerned with the losses in transformers for use with mercury-arc rectifiers, and introduces methods of calculating and testing the losses in these transformers independent of the rectifiers.

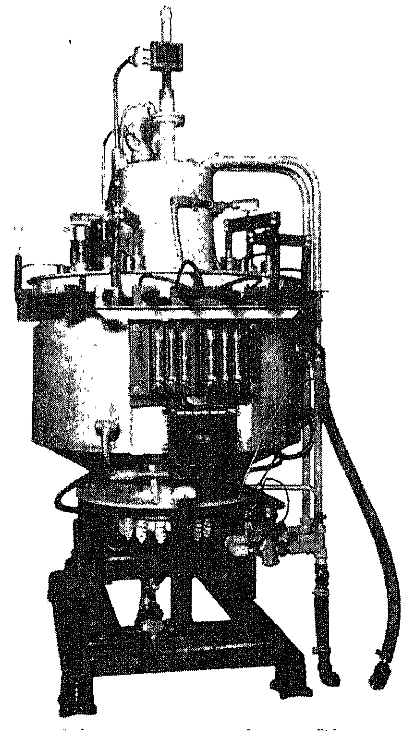


Fig. 1. Rectifier of recent design, with graphite anodes, subdividing grilles, and control grids

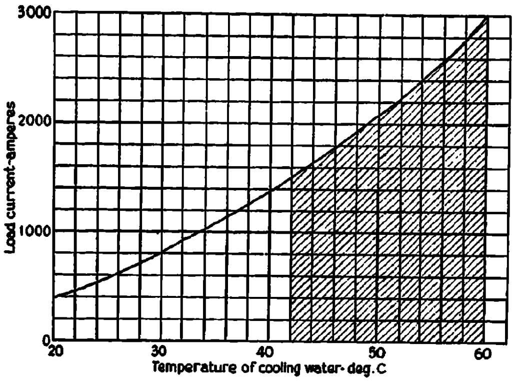

Fig. 2. Load-temperature curve for loads of 1 min. duration at 3,000 volts on a six-anode rectifier similar to Fig. 1, with 15-cm. diameter arms

pressure; or, conversely, lowered the vapor pressure for the same sparking potential by 50 per cent. Vapor pressure doubles for each 10 deg. temperature.

The current limitation is of a different nature. It is due to a complete utilization of the mercury vapor in the anode arms, the maximum load current being that which utilizes all the molecules of the vapor as positive ions to neutralize the electron space charge.

The vapor pressure in the anode arms is not completely determined by the temperature of the cooling water in the case of continued heavy loads, because of the temperature gradient in the iron wall and the iron-water boundary, and under some conditions, a pressure gradient in the mercury vapor due to convection of mercury spray and its vaporization in the arc stream. Differences as great at 10 deg. cent. between water temperature and equivalent vapor pressure have been observed and even greater differences may exist. Hence, when the water temperature is adjusted to give the maximum safe vapor pressure in order to carry the maximum load, if this load is maintained the pressure will rise above the safe value. This results in a load-time characteristic such as shown in Fig. 4.

A series of simultaneous measurements was made of vapor pressure in the anode arms and temperature in different parts of the tank, during normal low-voltage operation. It was found that with light loads the vapor pressure in the anode arm corresponds very closely to the temperature of the part just beneath the anode arm, and is nearly independent of the temperature of the rest of the rectifier.

ANODE HEATERS

The limits of vapor pressure are almost certain to be momentarily exceeded if mercury in a liquid state comes in contact with hot anodes or any hot surfaces near the anodes. In some of the early models it was observed when they were opened that the anodes and their housings were thickly coated with small drops of mercury which had condensed as the rectifier cooled. These rectifiers were known to arc back frequently within the period between 20 min. and 2 hr. after starting, which was about the range of time required under vaying loads for the anodes and housings to become hot enough to vaporize mercury rapidly, and thus lead to excessive local pressure with resultant arc-back. Heaters were therefore installed in the anodes and housings at a temperature higher than the body of the rectifier, so that condensation could not occur. The result was the entire disappearance of the 20-min. to 2-hr. arc-backs, and, in fact, of nearly all arc-backs.

VOLTAGE DROP

The pulse of a rectifier is the voltage drop between cathode and anode when the anode is positive. It is a valuable index of health, especially in studying or conditioning a new rectifier. For example, an exceptionally low voltage drop tells that the vapor pressure is abnormally high, and arc-back may be expected with continued load; a high voltage drop indicates excessive load, which must be reduced or the vapor pressure raised if reliable operation is to continue. If one anode has a higher voltage drop than the others it contains foreign gas, due either to leakage or incomplete exhaust; if lower, its grid has probably been injured during assembly or exhaust.

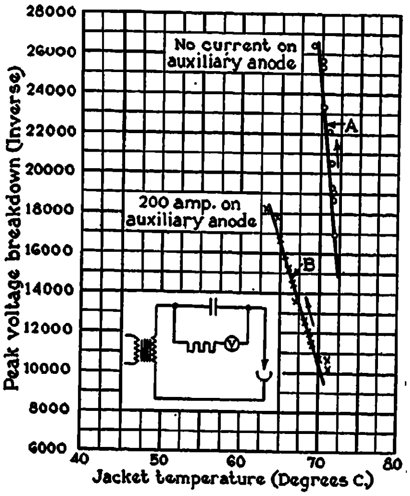

Fig. 3. Sparking potential of an idle anode in an iron-anode rectifier, as a function of mercury vapor pressure

The slope or "resistance" of the voltage—current characteristic is negative for small currents, zero for moderate currents, and positive for large currents, as shown in Fig. 5. The negative portion of the characteristic is well known. The positive portion is observable only with low-pressure arcs, and is due to the approach to complete utilization of all the gas. When volt-ampere characteristics are obtained for different vapor pressures, it is found that the current at which the characteristic becomes positive is proportional to the vapor pressure, as may be seen in the figure. This is to be expected from the point of view previously expressed that positive resistance is due to full utilization of the mercury vapor.

Using a peak-reading vacuum-tube voltmeter in a group of tests simulating operating conditions, it was found that arc-back usually occurs when the voltage drop exceeds about 50 volts. Hence the maximum load which a rectifier can carry may be predicted from the intersection of its volt-ampere characteristic with the 50-volt line. Excessive voltage drop is usually accompanied by surges which excite oscillations of the transformer system, sometimes of sufficient voltage to arc over insulation.

If the positive resistance shown in Fig. 5 represents a true instantaneous characteristic of the arc, it should be possible to operate such arcs in multiple for large currents without the use of stabilizing resistance or reactance. This was tested in a 24-anode rectifier, the anodes of which were arranged in two concentric rings of twelve each and connected in pairs to the terminals of a twelve-phase transformer, each pair consisting of one anode of the outer group and one of the inner group. The length of the arc path to the outer anode was sufficiently longer than that to the inner anode that an unfavorable condition for division of current existed.

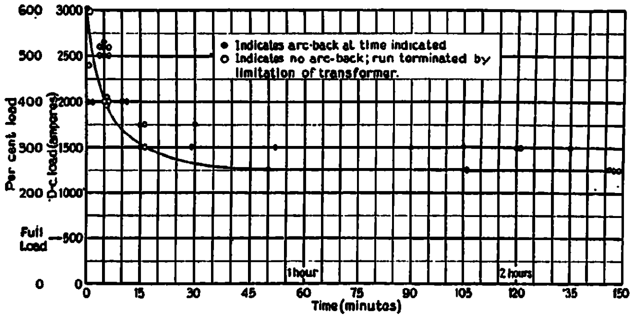

Fig. 4. Arc-back characteristic of same rectifier as in Fig. 3, at 3,000 volts and 60 deg.

From the characteristic given in Fig. 5 we should expect one anode of each pair to carry all the current for light loads for which the characteristic is negative, and for a small portion of the positive range, up to the current value at which the voltage drop is equal to the voltage drop for zero current of the other anode of the pair; at loads greater than this, both anodes of each pair will carry current, and will carry it more and more equally as the load increases. The current actually observed for several pairs of anodes conforms completely to the values predicted from the characteristic arc-drop curve.

As additional evidence of the approximately equal division of current, the rectifier was tested for current-capacity, first with one set of anodes alone, and then with the two sets in parallel. It was found that the rectifier would carry twice as much current with the parallel anode connection as with either set of twelve anodes alone. Further readings taken with an oscillograph agree with the load-limit test in showing that the load capacity is doubled by doubling the number of anodes and using them in pairs, each pair being in multiple without stabilizing reactance.

Geometry of Anode Arms

Since as previously shown the temperatures that determine the current capacity are almost entirely those near the anode arms, it may be anticipated that the important dimensions will be those of the arms. This has been found to be true. It has been shown, however, that for geometrically similar plain cylindrical arms, the capacity is nearly independent of the dimensions of the arms. The reason that the current does not increase with diameter is that the maximum safe operating temperature decreases as the diameter of the arm increases. Thus the total amount of vapor in the arm, and hence the current capacity, should remain about constant in agreement with observation.

The behavior is very different when the anode arm is subdivided so as to be equivalent to a group of small arms. If the part of the arm just below the anode is divided by metal vanes into narrow parallel channels, the limiting vapor pressure is determined by the dimensions of these channels and their distance from the anode, and is independent of the diameter of the arm. Under these conditions the current capacity is proportional to the square of the diameter, that is to the cross section of the anode arm. This is shown in Fig. 6.

This agrees with the previously described test for parallel operation which indicates that if any number n of adjacent anodes are grouped in parallel as a unit, without stabilizing resistance or reactance, the current which they can carry safely is n times that of a single anode. The group of parallel-connected anodes may

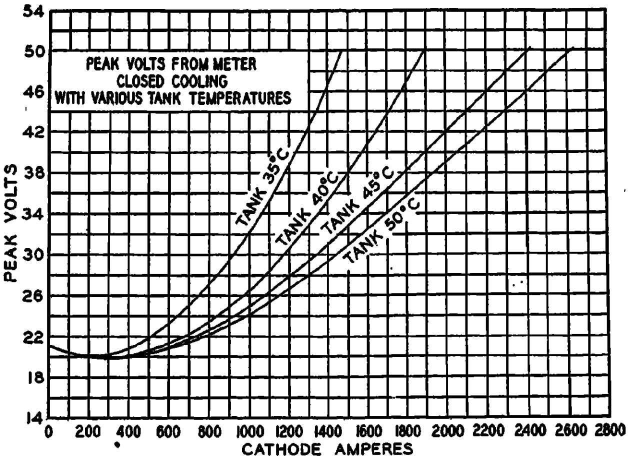

Fig. 5. Voltage drop in a mercury arc as a function of current

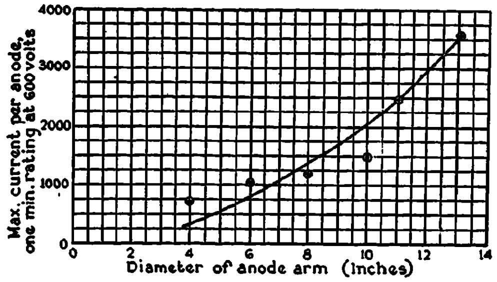

Fig. 6. Test points of current capacity for subdivided graphite arms. The solid line represents the theoretical limiting value of 4 amperes per sq. cm.

obviously be connected together inside the rectifier instead of outside, which is equivalent to combining them into one large anode with a number of parallel paths leading to it, each path similar in dimensions to one of the single anode arms. This is the principle of subdivided arms.

Their use has been very carefully tested, using partitions of different forms and dimensions, and anode arms from 15 to 33 cm. diameter. The results show that with a given "mesh" of subdividing partition, the current that can be carried is proportional to the total cross section of the arm, as it should be. The maximum operating vapor pressure, and hence the current per unit cross section, depend upon the dimensions of the partitions.

GRIDS AND THEIR USES

Grids or grilles consisting of parallel passages longer than they are wide may perform the function described above of enabling rectifiers to operate at a higher vapor pressure than is possible without these grilles. The sparking potential of a gas decreases with decreasing pressure, as is well known, to a minimum value, and then increases rapidly with further decrease of pressure. At pressures above that corresponding to the minimum, the sparking potential is higher the greater the distance.

The tungar rectifier operates above the minimum, *viz.*, at 5-cm. mercury pressure of argon. It might seem that advantage could be taken of this fact to increase the arc-back voltage of the tungar rectifier by increasing the distance between electrodes; for example, at 2-cm. distance the sparking potential is 1,800 volts. The answer is that it is impossible to maintain this distance under rectifying conditions, for the ionized gas that is left between the electrodes at the end of the rectifying cycle forms a conducting sheath around the positive electrode, building it out until its distance from the negative electrode is that corresponding to minimum sparking potential. This applies to all pressures higher than the "minimum" and all reasonable electrode distances.

It is evident therefore that high-voltage rectification can be accomplished, if at all, only in the range of pressure below the minimum point. In this range the sparking potential is higher the smaller the distance between electrodes. With an anode arm 30 cm. in diameter the effective sparking distance between anode and wall is of the order of 60 cm. At this distance the pressure of mercury vapor corresponding to a sparking potential of 6,000 volts is approximately 0.003 mm. The function of the grille is to decrease this distance and thus allow a higher operating pressure. For example, by placing a grille 5 cm. below the anode the distance is decreased from 60 cm. to 5 cm., and the pressure thus increased from 0.003 mm. to about 0.040 mm.

The form of the grid is important if it is to perform this function of shortening the distance between anode and body of the rectifier. Tests have shown that wire grids, unless their mesh is very fine, are not effective in shortening the distance, since the ions diffuse freely through the holes. On the other hand, partitioned passages or grilles like those described above do not allow ions to diffuse through, provided the length of the passages is large compared to their width.

Another use of the grid is to control the starting of an arc, rectifiers equipped with such grids being called thyratrons. Any type of grid can perform this function provided it is insulated, and the voltage that must be applied to it to allow or prevent starting of the arc depends upon its location and fineness.

One application of thyratrons is the use of the grid for obtaining automatic voltage regulation. The principle of this regulation is that the phase of the voltage applied to the grids is automatically advanced as the load increases. This is obtained by having the grid voltage derived from a current transformer in the line, so connected that its variable output voltage is added to a 90-deg. lagging constant voltage derived from a selsyn transformer. The constants are so adjusted that at light load the anode current starts late in the cycle, advancing with load until at the desired overload it starts at the earliest possible starting time, namely, the time at which the anode voltage rises above the rectified d-c. line voltage.

HOT-CATHODE RECTIFIERS

Hot-cathode rectifiers, although not yet developed for large capacities, have many features which make them attractive. One of these is the ease of control of the mercury vapor pressures. A single drop of mercury suffices and this may be located in the coolest part of the tube remote from the arc so that the temperature of this part will determine completely the vapor pressure throughout the tube. The rest of the walls may be as hot as desired, thus permitting a considerable reduction in size of the rectifier.

Another advantage of hot-cathode rectifiers is low voltage drop with resulting efficiency at low operating voltage. Three factors contribute to this low voltage drop. In the absence of mercury spray the distance between the cathode and anode may be short; an "efficient" cathode material, such as barium requiring but two watts per ampere, may be used; and a wide choice of gases is available. Thus hot-cathode rectifiers promise to fulfil the future requirements of low-voltage applications with an efficiency of 95 per cent or better at 250 volts, and well over 90 per cent at 100 volts.

Backfires in Mercury Rectifiers

Successful operation of mercury arc rectifiers requires the almost complete elimination of backfires. Studies made to eradicate this evil should recognize that backfires do not occur at some given stress, but are random in their nature. There is, however, an average rate of backfire which determines the reliability of a rectifier.

IN A mercury arc rectifier operating normally, each anode carries a large current when it is at a positive potential with respect to the cathode and a very small current (a few milliamperes) when it is at a considerable negative potential with respect to the cathode. It was found early that with the simplest and most obvious constructions this normal operation was not reliable, and was not reliable in an erratic way. An anode would function properly for perhaps thousands of cycles, and then suddenly fail to hold voltage when negative in some particular half cycle. With the usual rectifier circuits, such failures result in a short circuit and they are termed "arc backs" or "backfires."

The causes of these backfires are still not well understood, but it was found early that certain constructions reduced the likelihood of their occurrence. For example, cooling of the rectifier by introducing condensing chambers, water jackets, etc., keeps the vapor pressure low and reduces the backfire frequency. Also, moving the anodes away from above the cathode, placing them in shields, and placing grids in these shields such that they were interposed in the arc path, aided in reducing the chances of backfire. However, these remedial measures greatly increased the size and cost of rectifiers; and increased their arc drop, thus decreasing the efficiency. Consequently the whole design of the present day rectifier is predicated on the reduction of backfire frequency, and the means employed result in a rectifier for 600-volt service which is nearly as expensive as a rotary converter, scarcely more efficient and probably still less reliable. Clearly, research devoted to advancing the application of mercury arc rectifiers must consist of a study of backfire which will yield means for reducing the tendency without losing the attractive features of mercury arc conversion.

BACKFIRES—A RANDOM PHENOMENON

A striking feature of rectifier operation is the erratic manner in which backfires take place. Yet the great significance of this erratic behavior and its implications as to the operation which may be expected, do not seem to have been generally grasped. It is essential to recognize that except for backfires due to certain grosser causes, which will be mentioned later, backfires are inherently a random phenomenon in that they do not take place immediately when a definite limiting stress is reached, such as, for example, when some limit of current, voltage or vapor pressure is exceeded. Backfires occur in a random manner under all operating conditions, but with an average frequency which depends on the conditions of operation. Hence a backfire is very unlike the breakdown of a spark gap, which is certain to take place if the potential difference across the gap is increased beyond a definite value. Backfires do, however, resemble many other examples of random or inherently erratic phenomena well known in physics, such as the Brownian movement, the disintegration of radium, or the fluctuation in the density of a gas when sufficiently small volumes of the gas are considered, and like these phenomena, backfires probably depend for their occurrence upon aggregates involving relatively small numbers of atoms, molecules, ions or electrons.

The entirely random occurrence of backfires in time may be illustrated by Fig. 1, which was obtained with a small metal tank rectifier, with all controllable variables held as nearly constant as possible. The probability of backfire of a rectifier is a particular condition and during a short time interval Δt may be defined as follows. Imagine a large number of tests N, made with a rectifier under identical conditions, the

---

From "Backfires in Mercury Arc Rectifiers," (No. 31-132) to be presented at the A. I. E. E. South West District meeting, Kansas City, Mo., Oct. 22-24, 1931.

time duration of each test being the interval Δt. Suppose that backfires occur in a certain number of these tests n, but not in the others. Then $\frac{n}{N}$ will be the probability of having a backfire in the time interval Δt, and if we write $\frac{n}{N} = p\,\Delta t$, then p is the probability of backfire per unit time.

It can be demonstrated that if the probability of backfire remains constant, and if the time intervals between successive backfires are observed, then the proportion of these time intervals which is greater than a given time T is e^{-pT}. That is $\frac{m}{M} = e^{-pT}$, where m is the number of intervals greater than T in length, and M is the total number of intervals. This relation has been confirmed experimentally with a metal tank rectifier having a constant current arc going to one anode and a negative test voltage on the other, with the result shown in Fig. 2.

The state of a rectifier with respect to backfire is properly described when a mean frequency of occurrence of backfire is given. It cannot be described by saying that the rectifier is operating above or below backfire limits, inasmuch as there are no definite backfire limits. The mean frequency of backfire depends on the construction of the rectifier, and on the conditions under which it operates. There are probably no commercial rectifiers which have a mean backfire frequency of zero; but a mean frequency as small as once in a few years is of course low enough to give more than the degree of reliability satisfactory for operating purposes. The backfire frequency of successful rectifiers in the field seems to be of the order of several per year.

TESTING OF RECTIFIERS

Commercial tests on rectifiers are made to determine their quality, which must be found in terms of an average backfire rate. Since this rate is very low for commercial rectifiers, its determination by usual tests is practically impossible. For example, suppose that a large number of rectifiers were made with such uniformity that each had an average backfire rate of once per month. If they were tested by the manufacturer for one month, which is impractically long, the mathematical probability is that 37 per cent of the rectifiers would not backfire, another 37 per cent would backfire once, and only 26 per cent would backfire twice or more. Consequently such a test would not show the true reliability of the rectifiers.

The way out of this dilemma seems to be to test the rectifiers under abnormal conditions which would make the average backfire rate countable in a reasonable length of time and to have data which will permit extrapolation for determining the backfire rate under normal conditions. For example, if the dependence of backfire rate upon test voltage is well established for a given type of rectifier, the tests might be made at such overvoltage as will give a countable rate in one day. Extrapolation to normal voltage would then give the expected backfire rate under normal conditions.

The variation of backfire rate with voltage for a small two-anode metal tank rectifier is shown in Fig. 3. The average breakdown rate was found to vary exponentially with the voltage. Current of 48 amperes was kept flowing to one anode, and a negative voltage was continuously applied to the other, grid-glow tube relays being used to record the backfires automatically. Tests were made at various times, and because of day to day variation as the quality of the rectifier changed somewhat for unknown reasons, different straight lines were obtained. All the data lay between the dotted lines shown in the figure.

Both iron and graphite anodes are extensively used by rectifier manufacturers. Tests at abnormal voltages on the relative average backfire rates with these two materials have shown that a few more backfires occur in a given time with iron than with graphite, but the

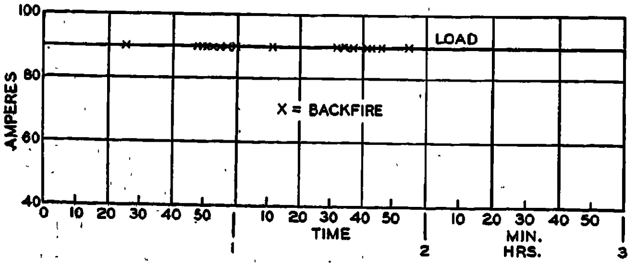

Fig. 1. (Above) Random occurrence of backfire on a small metal tank rectifier

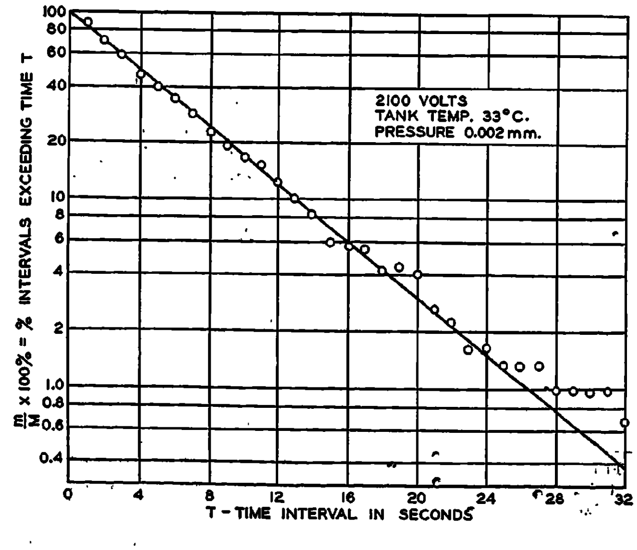

Fig. 2. (Right) Percentage of intervals between backfires exceeding time length T, in terms of time T

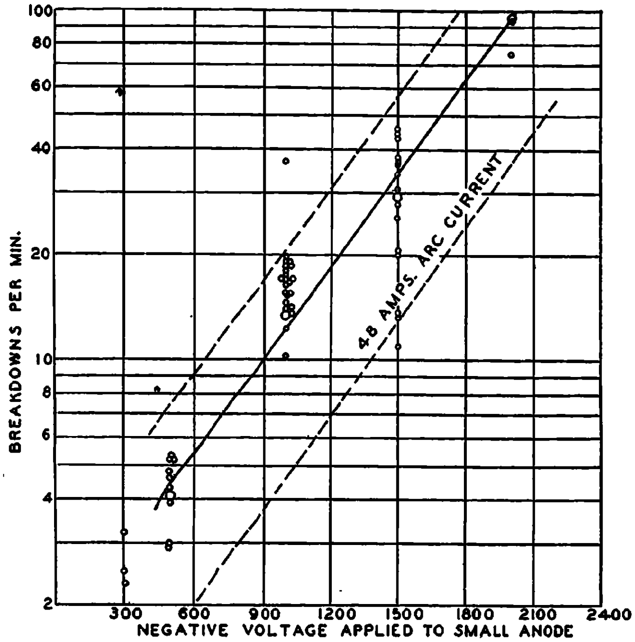

Fig. 3. Variation in average backfire rate with voltage for a metal tank rectifier

difference is no greater than day to day variations with either material. Consequently, no decided advantage of either material is indicated from a standpoint of backfire rate alone.

CAUSES OF BACKFIRES

In addition to random backfires, certain grosser backfire causes which will not be random may occur in practical rectifiers. An example is the starting of an arc due to the blowing up of a conducting deposit formed over an insulator from anode to tank, the action being similar to that of a fuse. Direct observation shows, however, that such grosser causes are avoided in well-built rectifiers and that most backfires occur directly on the anode surface. It is these latter backfires, which are of the random type, to which we wish to give further consideration.

According to present available theories of the cathode of an arc, backfire should never occur without some initiating circumstance foreign to the kind of discharge taking place just previous to the backfire. A glow differs from an arc in that it requires several hundred volts at the cathode for its maintenance. In rectifiers, the construction and vapor pressure are generally such that it is not possible to hold a self-maintaining glow with the available negative voltage which is impressed on the anode. However, with normal negative voltage on one anode and an arc playing to the other, current flows to the negative anode which does not differ essentially from a glow, except that it is not self-maintaining. Consequently both the glow and the non-self-maintaining discharge will be considered together as the back current discharge.

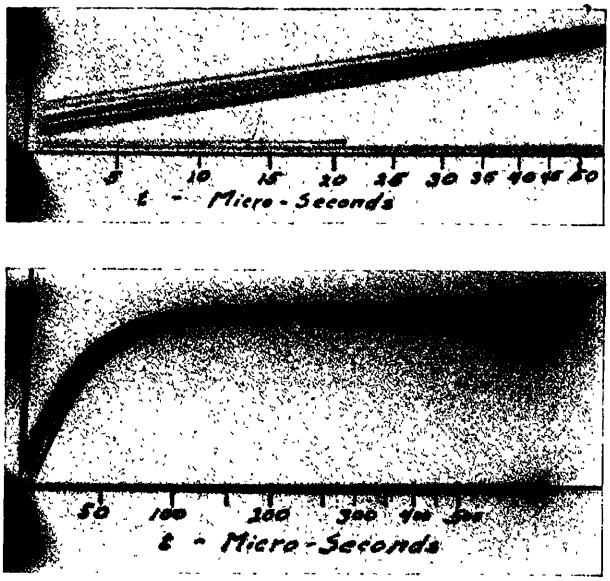

Fig. 4. Typical cathode-ray oscillograms showing time duration of backfire causes

A backfire consists in the sudden substitution of an arc for the normal back current discharge. Somehow, the conditions for the maintenance of the cathode of an arc must suddenly set themselves up. The conditions required at the cathode of an arc as predicted by present theory are such as should not occur spontaneously so far as the intrinsic characteristics of the back current discharge go. The conditions required at the cathode of an arc, according to present theories, call for either a very high temperature or a high current density.

With the low current density in the back current discharge, it is not possible to obtain sufficiently high temperature to produce an arc so long as the current is uniformly distributed over the anode. A sufficiently intense field at the cathode surface (10^6 volts per cm. or more) could initiate the cathode of an arc, but due to the high concentration of positive ions necessary such a field would require a current density of several thousand amperes per square centimeter. The current density in the back current discharge is only a few microamperes per square centimeter. The variation of current density over a very small area of surface might allow sufficiently high instantaneous densities, but such small areas must not be considered because the cathode of an arc is unstable if the current to it is less than 0.05 amperes.

Scrutiny of the back current discharge through the spectacles of present theories of the cathode of an arc fails to reveal the causes of backfire, provided the cathode surface be regarded as homogeneous. We must then consider the result of possible contaminations on the surface and flaws in the electrode material.

One type of backfire cause is suggested by tests made with a tube containing two graphite electrodes and equipped so that a small insulated tungsten wire could be caused to make or break contact with the cathode. Voltage was applied to the electrodes of the tube and when it was sufficient to form a stable glow, backfires could be produced by making or breaking contact on the cathode with the small insulated tungsten tip. The cause of the backfire is to be sought in the very high current density at the lost contact point. This very high density will result as the area common to the point and electrode shrinks to zero during separation.

Several backfire causes may now be given. A very obvious one is contacting mercury drops thrown from the cathode. Small conducting particles such as iron rust or scale may contact with the anode and cause backfire in the same way, and in this an argument for extreme cleanliness in rectifier assembly is found.

Particles may detach themselves from the anode itself. It is well known that the anode suffers a slow disintegration known as sputtering, due to the back current discharge. Although the sputtered particles may consist largely of individual molecules, it is believed that larger particles are also detached. The presence of impurities would tend to cause a more frequent detachment of larger particles.

From this discussion on possible backfire causes it would be expected that the magnitude of the back current is important. If the back current is large, then the particle size necessary to cause backfire may be smaller. Also, the sputtering of the electrode will be more rapid with a large back current, and large particles are more likely to be detached or loosened. Any means which reduce the back current to the electrode, such as grids, shields, etc., must also reduce the frequency of occurrence of backfire. Experience shows this to be the case.

Another cause of backfire suggested by Langmuir is the formation of insulating patches on the electrode with dielectric failure of the patch as it becomes charged by back current. These patches are made up of impurities, oxides, or what not, and because of the small amount of material in their make-up their development to large sizes will be a random occurrence. Other experimenters also have surmised the existence of such insulating layers.

DURATION OF BACKFIRE CAUSES

The random manner of occurrence of backfire as well as considerations of the preceding section make us believe that backfire causes involve only a small amount of matter. Since the amount of matter involved is very small, we should expect also that the time involved by backfire cause would be very small.

Cathode-ray oscillograph tests have been made to determine the time duration of backfire causes. A small metal tank rectifier was used, and continuous current was run to one anode and continuous negative voltage was applied to the other. A high resistance was placed in series with this anode so that in the advent of a backfire to it, a current too low for maintaining the cathode of an arc would flow. The cathode-ray oscillograph had a Norinder relay which was actuated by the backfire, and the voltage between tested anode and cathode was applied to the deflecting plates, typical oscillograms being shown in Fig. 4. The initial drop in voltage on the occurrence of a backfire does not appear because of a time-lag of three microseconds in the action of the Norinder relay. The time during which the voltage is very low is the time duration of the backfire cause. The finite rate of recovery of voltage after the backfire is due to electrostatic capacity of the potentiometer by which the oscillograph was connected to the rectifier. The duration of the backfire causes was usually less than five microseconds.

Losses in Mercury Rectifier Transformers

Improved methods of calculating and testing the losses in transformers for use with mercury arc rectifiers are now available. These methods greatly simplify the mathematics involved in loss calculations and make it possible to measure directly the losses of transformers independent of the rectifiers.

By

Pittsfield, Mass.

DETERMINATION of the losses in transformers connected for use with mercury arc rectifiers involves difficulties not present in usual power transformers, due largely to the shape of the secondary current wave delivered to the rectifier. In the past, various tables have been published which give calculations of effective values of current and the losses in transformers in various rectifier connections. These calculations are based on the assumption that

---

From "Losses in Transformers for Use with Mercury Arc Rectifiers," (No. 31-70) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

the secondary current waves are rectangular in shape and that the effective resistance of the transformer windings is the same at all frequencies. However, calculations based on these assumptions may be considerably in error as the current wave contains a large number of harmonics which are influenced somewhat by the reactance of the circuits, and the effective resistance of transformer windings varies with the frequency. Using the d-c. resistance of the windings and the theoretical values of the harmonics as explained below, much more accurate calculations of transformer losses result.

A rectangular secondary current wave can be analyzed into a series of terms in which the amplitude of the nth harmonic is:

$$A_n = \frac{2J}{n\pi} \times \sin\frac{n\pi}{P} \tag{1}$$

in which J = magnitude of direct current

P = number of phases

The effect of the reactance of the circuit is to alter the assumed rectangular wave shape by sloping the sides of the wave, as a definite time is required for the current to rise to its full value at the beginning of the conduction period and fall to zero at the end. The effect is to reduce the magnitude of the harmonics in the current wave.

A formula has been developed for calculating the effective winding resistance in which

$$\text{Watts eddy current loss} = 0.86\,Y X^{1.875} \tag{2}$$

where

X = frequency

Y = the sum of the other factors which determine the eddy loss, and is constant for a given winding

The actual magnitude of the various harmonics in the primary and secondary current waves of a representative six-phase rectifier connection was measured, and from these readings and the corresponding winding resistances, the losses were calculated and found to be the same as would be obtained in the d-c. resistance of the windings, and the theoretical values of the harmonics as determined from equation (1) were used to determine the losses. This indicates that for the average circuit, the effect on the losses of the increase in resistance at the harmonic frequencies is approximately balanced by the effect of the reduction in magnitude of the harmonics due to the reactance of the circuits. These results hold with satisfactory accuracy for the other commonly used rectifier circuits.

The calculation of losses based on the d-c. resistance of the transformer windings and the theoretical values of current harmonics for rectangular secondary current waves has been recommended for the proposed A. I. E. E. Standards for Mercury Arc Rectifiers. This method eliminates involved mathematical calculations and factors based on design features. Also, the calculations may be checked by the purchaser and used to determine the safe size of cables for making connections.

TESTING METHODS

Three methods of testing are proposed for the three classes into which all of the commonly used rectifier connections fall. For all tests, rated sinusoidal current at rated frequency is held in the primary, and the secondary windings are short-circuited as follows for the various types of connections.

The six-phase multiple wye secondary connection of transformers is shown in Fig. 1. For this type of connection, the copper losses measured with one-half of the secondary windings of each phase short-circuited,

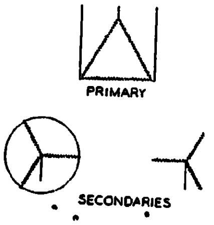

Fig. 1. Test connections for six-phase multiple wye transformers

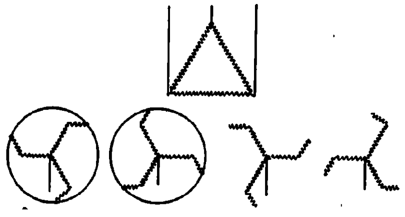
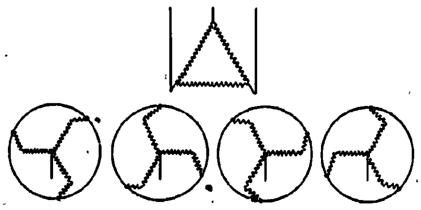
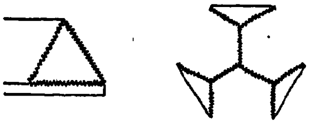


(a) TEST No. 1

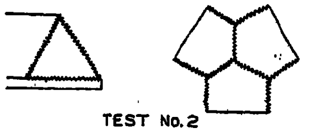


(b) TEST No. 2

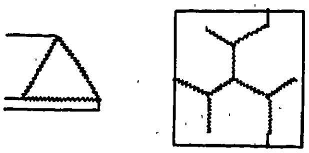
Fig. 2. (Left) Test connections for twelve-phase multiple wye transformers



TEST No. 1



TEST No. 2



TEST No. 3

Fig. 3. (Right) Test connections for six-phase forked wye transformers as indicated by the straight lines, equal the loss which would be obtained under rectifier operation.

For the twelve-phase multiple wye connection, two tests are made. The first is with one-half of the secondary coils of each phase short-circuited as shown in Fig. 2(**a**), and the second is with all of the secondary coils short-circuited as shown in Fig. 2(**b**). Denoting the losses measured in the two tests by L_1 and L_2 respectively, the copper losses which would be obtained under rectifier operation will be:

$$W_{cu} = 1.12\,L_1 - 0.12\,L_2 \tag{3}$$

For six-phase forked connections, three loss measurements are made with the secondary winding short-circuited as shown in Fig. 3. Denoting the loss measurements for the three tests by L_1, L_2, and L_3 respectively, the copper losses which would be obtained under rectifier operation will be:

$$W_{cu} = \frac{L_1 + 2\,L_2 + 3\,L_3}{6} \tag{4}$$

Since the voltage wave impressed on the transformer primary approximates a sine wave when the rectifier is fed from a system whose capacity is reasonably large, the iron loss should be measured in the same manner as for ordinary power transformers. It is therefore possible to test the main transformers of the various rectifier connections independently of the rectifiers, and determine with satisfactory accuracy, the losses in both copper and iron which would be obtained under rectifier operation.

Corona and Line Surges

Tests on an experimental transmission line show that from the standpoint of damping transient surges there is no advantage in operating the line at so high a voltage that the conductors will be in corona.

By
H. H. SKILLING
Associate A. I. E. E.
Stanford University
California

FREQUENTLY in technical literature the suggestion has been made that power-frequency corona would increase the damping of transmission-line surges. A recent repetition of this ideal, all unsubstantiated, led to the present investigation the results of which have shown that the presence of corona is of no value in this connection; its damping effect in any case is only slight and often is more harmful than helpful.

A surge on a line in service, if due to lightning, may have a voltage far exceeding the corona-forming voltage of the line; in such a case the chief attenuation will be due to corona. To explain further, the surge itself will ionize the air around the conductor and in so doing, the energy stored in the surge will diminish; the maximum voltage of the surge will decrease accordingly. Ionization will continue as the surge travels along the line as long as the voltage of the surge is above the corona limit; thereafter attenuation will be much slower, for the main damping influence will have lost its effect. This ionization is a real phenomenon, since the corona produced by a single impulse of extremely short duration may be seen clearly in the dark, and the noise that a surge makes as it passes may be heard quite as easily.

It is evident that a previous condition of ionization about the conductor due to overstress at power frequency would affect the rate of loss of energy from the impulse; but in what way may be found only by experiment. To determine the nature of this relationship, therefore, this investigation was undertaken.

TEST EQUIPMENT

Apparatus was devised by which traveling impulses with crests as high as 440-kv. could be sent along a 1,000-ft. line. For furnishing these high-voltage impulses, an adaptation of the "lightning generator" was used. A condenser charged by power-frequency current had its energy suddenly released by the breakdown of a sphere-gap, and as fast as the inductance of the condenser circuit permitted, the condenser voltage appeared between the sending end of the transmission line and ground. This voltage and current proportional to it sent along the line a wave the magnitude of which was increased with time, until a sphere-gap at the sending end of the line sparked to ground; the sending voltage then fell to zero almost immediately and remained negligible thereafter while the wave traveled out along the line and was measured. Ordinarily, the trip-gap was set to discharge the condenser at 375 kv. It was found convenient to chop the impulse by means of the

---

Written specially for ELECTRICAL ENGINEERING. Not published in pamphlet form.

gap at the sending end of the line at some value between 100 and 200 kv. The time required to build up such a voltage was about 0.05 microsec. The critical corona voltage of this 1,000-ft. line at 60 cycles was found to be about 30 kv. or 43 kv., crest value.

Voltages were measured at each end of the line and at several intermediate points by means of sphere-gaps. If the observer were far enough from the noise of the laboratory, an interesting supplementary comparison of impulse voltages was possible by listening to the sound that accompanied impulses of voltage higher than the critical corona value. A click somewhat like the noise made by dropping a pencil indicated that a wave had passed, and in passing had ionized the air; a second or so later would come the crash of the sphere-gaps in the laboratory; and perhaps between the two, the snap of the measuring sphere-gap. On a bright day the ear was more to be trusted than the eye in reporting events.

The rapid attenuation of surges when their voltages were higher than the corona-forming voltage of the line, and their slower attenuation near that voltage, is shown graphically in Fig. 1. The most evident disclosure of these curves is that the impulses, at whatever voltage they may be sent, are rapidly cut to a crest value between 25 and 50 kv. Thereafter attenuation is so slow that at the terminus of the 1,000-ft. line, it is difficult to distinguish between a wave that started with a crest of less than 100 kv. and another that started at more than 200 kv.

SURGES SUPERPOSED ON DIFFERENT 60-CYCLE LINE VOLTAGES

When the action of the impulses was moderately well understood and the technique of measurement was developed sufficiently to give assurance of significant results, the line was tested while in corona. The apparatus permitted the impulse voltage to be superposed suddenly on a steady 60-cycle voltage. The phase of the corona-voltage cycle at which the impulse was applied was definitely known, and in the first work the impulse "struck" at the instant of maximum 60-cycle voltage. The sending-end sphere-gap now did not measure the impulse voltage alone, but the sum of impulse and 60-cycle voltages, added when the polarities were the same and subtracted when they were opposite. The same is true of the measuring sphere-gap at intermediate points on the line.

These combined impulse and line-voltage measurements represent the values in which the engineer is interested, since the strongest impulse that may be propagated over a line is one which will not flash across a string of insulators when added to the line potential at that instant. Whether or not a surge still will be dangerous at some crucial point, as, for instance, at a transformer bank, depends upon whether at that point the insulation will fail under the combined action of normal line and impulse voltages. Hence, while the sphere-gap does not measure the impulse voltage directly, it does give an indication of danger. At the end of the line, reflection of the impulse adds to the danger; the resultant crest voltage at the terminus may be found by a simple computation, or it may be measured directly.

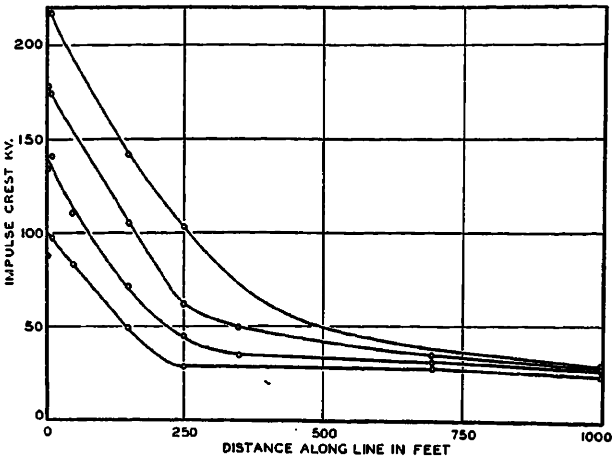


Fig. 1. Attenuation of transmission line surges. Note rapid reduction above the corona-forming voltage (30 kv.)

The presence of corona was found to make a measurable difference in the behavior of the high-voltage impulses. When the impulse was thrown on the line with the same polarity as the 60-cycle voltage, the rate of attenuation of the impulse was lessened to a marked degree, and the danger at any point was correspondingly great. When polarities were opposite, the 60-cycle voltage had less total effect; attenuation of the impulse was more rapid, which lessened the danger at any point along the line, but the danger due to reflection at the terminus was much greater.

The foregoing effects are shown in Fig. 2, where the crest voltage of a given impulse after traveling a certain distance is shown as a function of the 60-cycle line voltage. The lower pair of curves intersects the axis at a value corresponding to the 150-ft. point on the 133-kv. curve of Fig. 1. In like manner, the upper curves intersect the axis at a value corresponding to the 50-ft. point. These points on the two figures must therefore indicate the same impulse crest because they represent identical conditions. For the other points of Fig. 2 the impulse was superposed upon different 60-cycle line voltages. Points determined when the impulse and 60-cycle voltages were of the same polarity are marked with "plus" signs; points representing opposite polarity are indicated by "minus" signs.

SURGES APPLIED IN DIFFERENT PHASE RELATIONS

Apparently, attenuation of the impulse is not altered by line voltage unless the line voltage is high enough to produce corona, although this cannot be proved; however, the belief is supported by other tests in which the impulse was applied in various phase relations with respect to the corona-voltage cycle. With 40 kv. at 60 cycles applied, and with the gap at the sending end of the line retaining a fixed spacing, the moment of applying the impulse was shifted by 60-deg. steps. With the sending-end sphere-gap setting the same as used in obtaining the data for Fig. 2 (to give an impulse of 133 kv.) the impulse crest voltage without 60-cycle line voltage was measured at a distance of 150 ft. from the sending end; then 40 kv. was applied and the impulse was impressed at the same instant at which the 60-cycle voltage reached a maximum of the same polarity. These measurements were followed by another with two voltages of opposite polarity. These are shown in Fig. 3, the radius of the circle being a measure of the impulse voltage alone; the vector drawn upward (83 kv.) indicates the resultant impulse voltage when the polarities were the same, while the vector pointing downward (62 kv.) gives the resultant voltage when polarities were opposite. Similar measurements were made with the impulse applied 60 and 120 deg., respectively, after maximum line voltage first with one polarity and then with the opposite. Results of these tests are indicated also in Fig. 3.

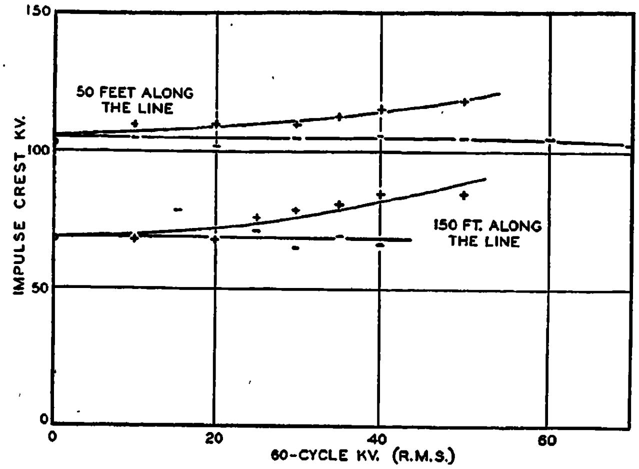

Fig. 2. Effect of different line voltages upon attenuation of 133-kv. surges

+ indicates surge and line voltage of same polarity
− indicates surge and line voltage of opposite polarity

For the first two cases (impulse voltage superposed upon a 60-cycle maximum of the same polarity and of opposite polarity, respectively) the expected change in rate of attenuation was observed; for the four intermediate phase positions there was no significant difference from attenuation without 60-cycle voltage.

TEST RESULTS ANALYZED

Space charge about the conductor when in corona seems to play an important role in aiding or impeding the attenuation of impulses. That the chief attenuation of the impulse is due to ionization is evident because (1) the impulse may be seen and heard and so must dissipate energy; (and 2) attenuation is rapid above the corona-forming voltage and slow below it. If 40-kv. power-frequency voltage be applied to a line that permits corona at 30 kv., there will be a zone about the conductor in which the potential gradient is the critical gradient of air (about 30 kv. per cm.); the gradient cannot be greater because air under a greater stress would ionize until the resulting space charge reduced the gradient to the critical value. (Since the times involved in 60-cycle changes of current and voltage are so vast compared to impulse times, the 60-cycle conditions existing at any moment may be considered fixed.) This cushioning action of the space charge makes possible the maintenance of a line voltage greater than the corona-forming voltage, for without such protection the air would continue to be broken down as fast as ionization by collision could take place; and were this the case, no reasonable amount of power could sustain a voltage substantially above that at which corona first appeared.

In the light of the foregoing, if an impulse voltage of the same polarity as the 60-cycle line voltage should occur, and if the 60-cycle voltage already has produced corona and hence protected itself by forming a space charge, it will be impossible for the impulse to attenuate by ionization to a voltage below the 60-cycle value. The cushioning effect that protects the 60-cycle voltage also will protect the impulse voltage. This is doubtless the reason that as soon as corona appears about the line, impulses are found to be attenuated more slowly if they are of the polarity of the line voltage. If they are of the opposite polarity, the space charge has the contrary effect; instead of lessening the gradient in the neighborhood of the wire as the impulse passes, it increases it. Presence of the space charge increases the electric field and thereby increases the energy loss, thus increasing the attenuation.

Without more quantitative information about energy loss from impulse voltages, it is impossible to predict the comparative efficacies of a given intensity of corona toward decreasing and increasing the attenuation of surges of similar and of opposite polarities. In the latter case, however, as expected and shown experimentally, the potential due to space charge is a smaller fraction of the impulse potential and will have a correspondingly lesser effect.

The wave shape of the impulse, that is, the function of time which describes the voltage at a point, also will influence the rate of attenuation of the impulse crest. An impulse shorter than 1 microsec. is considered fast, but ionization by collision is tremendously faster; hence a protecting space charge will be built up by the impulse itself as it travels along the line. If the wave is not sharp-crested but has a flat top, the latter part of the wave will be protected by space charge formed at the expense of the part preceding. While all of the wave eventually (if the line be long enough) will become reduced to the corona-forming voltage of the line, the front of the wave will lose energy most rapidly at first, and the crest voltage will diminish more slowly. No such action is possible in the case of a short wave, which rises quickly to a crest and as quickly falls. Space charge of enough intensity to protect the maximum voltage is formed only by the peak itself, and the wave immediately passes on to less ionized and unprotected sections. A long, flat wave, then, is less rapidly attenuated, and therefore is more dangerous than a short, sharp wave.

CONCLUSIONS

Work on attenuation of surges has been described in previous Institute publications (the most recent of these may be found in the July 1931 issue of ELECTRICAL ENGINEERING, pp. 478-502). Results of the present study are in such complete agreement with previous results that, for the most part, the conclusions reached may be quoted from the summary of one of the earlier investigations of Conwell and Fortescue, (A. I. E. E. TRANS., July 1930, p. 872) whose experimental work is of great interest in the light of the theory here presented:

> 1. "Considering crest voltage of the original surge and its attenuation, the attenuation is increased with crest voltage over the length of line used. The rate of increase in attenuation is much more rapid when the surge voltage exceeds the corona point of the line.
>
> 2. "Considering the relation between the length of wave and its attenuation, the short wave attenuates more rapidly than a long wave of equal crest voltage.
>
> 3. "Considering the effect of distance traveled on wave shape, with increased distance there seems to be an increased tendency to slope off the front of the wave and to increase the length of the tail. This change in form is more accentuated above the corona point."

To these now may be added another:

> 4. Considering the effect of power-frequency corona about the line, it will retard the attenuation of a surge of its own polarity, but will have little effect on a surge of opposite polarity.

The amount of attenuation is of great practical interest and there may be significance in a comparison of present results with those of Lee on the Wallenpaupack-Siegfried line. (TRANS. A. I. E. E., Vol. 48, p. 471.)

The line considered as the basis of this article was similar to the line considered by Lee, but reduced to one-tenth size; that is, the conductor considered in this article was about 10 per cent of the diameter of his and displayed corona at 28 kv. (r. m. s.) instead of at about 280 kv. The surges used were near 220 kv. while the lightning surge recorded on Lee's line started at 2,230 kv.

In becoming proportionately attenuated, his surge traveled 100 times as far as those mentioned in this article, or in the ratio of 10^2. These ratios were used in making up Table I: voltages of the line considered in this article are multiplied by 10; the distances by 100.

Included in the tabulation is a set of computed voltages that result from assuming that the energy lost (as the surge travels) is proportional to the voltage of the surge. This assumption is arbitrary, but agrees impressively with Lee's results and with those of this article as shown in the four curves, Fig. 1. Since energy is proportional to the square of voltage,

$$\frac{d}{dx} E^2 = - k (E - e)$$

where E is surge voltage, e is corona-forming voltage, k is an experimental constant, and x is distance along the line. The solution is

$$x = m [n - (E + e \log \epsilon (E - e))]$$

where m and n are constants involving k and the initial voltage. The computed voltages fit nicely into the tabulation, and differences can be explained as experimental error, line resistance, and (most important) change of wave-shape as the impulse travels.

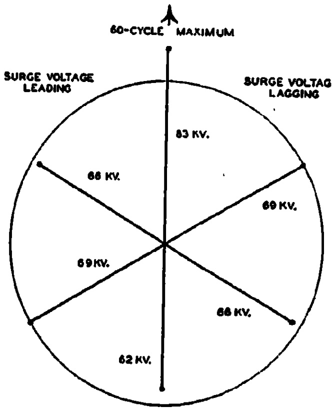

Fig. 3. Diagram showing surge-voltage measurements 150 ft. along the line with 133-kv. impulses applied in different phase relations with respect to the 60-cycle, 40-kv., line voltage

Radius of circle (68 kv.) indicates surge measurement with zero line voltage; arrow at top shows "in phase" position

These results imply that the "effective range" of a lightning surge is nearly proportional to the voltage of the surge, and to the corona-forming voltage of the line.

Dr. Harris J. Ryan and Dr. Joseph Carroll by guidance and aid have made possible the study leading to this paper.

Communication Plays its Part in Electric Power System Operation

Present day electric power systems, with their complex and far-flung interconnections, cover such large areas that the communication lines serving them have become almost as important as the power lines themselves. In the five articles on this and the following nine pages fundamental requirements of the electric utilities are outlined, and the communication schemes used by four typical operating companies are described.

ELECTRIC LIGHT AND POWER in all its perfection is not entirely independent of several other agencies of public service. Not the least of these is communication, which makes the light and power system the living organism it really is. Because the electric power system is everywhere, far flung in supply centers and activities, it is more dependent upon communication in the discharge of its obligations than are most other forms of business. This agency serves to coordinate the widely separated elements and thus plays a big part in unifying the operation of electric power systems. This is a necessary adjunct to the provision of satisfactory service to customers; for although a properly designed and constructed system, adequate tools, and able personnel, all are essential, yet no adequate service is rendered, and hence no revenue earned, until these elements are coordinated and unified.

This group of five articles is based upon five papers presented as a symposium at a session of the Institute's 1931 summer convention. They were prepared jointly by a total of six engineers of leading power companies, in collaboration with three communication engineers of the Bell telephone system, and therefore represent the joint efforts of those engineers most intimately connected with the needs of a power system and those having the best knowledge of modern developments in the communication field.

All five articles stress the importance of providing efficient and uninterrupted communication facilities for operating personnel. In most cases these facilities are provided by networks of interconnected privately owned and Bell system lines, although in one case carrier current furnishes the principal communicating medium. One article deals with a joint study between telephone and power company engineers, when the entire communication system of the power company was overhauled thereby effecting many improvements. Another article of the group describes the special communication facilities arranged by one company for handling customers' calls. Still another narrates in some detail how a special remote-metering system was installed, by which means continuous and practically automatic direction of load-scheduling activities was achieved.

The first article, which outlines the power company's principal requirements and suggests methods for meeting them, follows immediately.

Underlying Considerations of the Problem Outlined

By

E. C. BRIGGS Non-member — Ohio Bell Tel. Co. Cleveland, Ohio

EFFECTIVE COORDINATION of the activities of an electric utility necessitates the establishment of communication channels for the continuous flow of information into organization centers, and the prompt transmission of orders and suggestions from these centers to the points where action is taken. Voice communication appears to be especially adapted to meet these requirements, as is evidenced by the fact that about 85 per cent of the average electric utility's communication expense is for transmission of the spoken word.

From "Communication Services of Electric Utilities, Underlying Considerations" (No. 31-104) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

The work of an electric utility may be considered as being divided into the following three general classes:

1. Operating activities including dispatching, generating and substation operation, emergency line patrolling and repairs.
2. Customer service activities embracing all contacts between the utility and its customers.
3. Administrative activities including administrative sales and business functions as differentiated from service functions.

OPERATING ACTIVITIES

A typical organization chart for the handling of activities classed as "operation" is shown in Fig. 1. This indicates the communication channels usually necessary for the efficient flow of information between controlling centers and points where action originates. Communication facilities for such activities need to be:

1. Easy to operate and conveniently arranged.
2. Available at times when power facilities are in trouble.
3. Of such quality as to permit conversations to be carried on with ease.
4. Protected so as to be safe for use at all times including periods of system disturbances.
5. Of sufficient capacity so that under the *worst* emergency conditions no serious delays will be experienced in restoring electric service.

Heavy or important traffic requires the establishment of direct channels. Where continuous service must be provided, two or more independent paths are essential and these should be so routed that troubles on one will not affect the other.

Communication channels often are terminated at dispatching points in a cordless type of board where answering, ringing, and monitoring features are obtained by merely operating a key. This type of equipment appears to be suitable for use where no more than 50 channels are to be terminated, or where the required number of simultaneous through connections does not exceed five. Where more than these are involved, cord and plug boards usually are installed.

Teletypewriter apparatus is used to some extent in transmitting and recording routine information, such as meter readings and switching orders, and there is some probability that this equipment will provide a valuable supplement to the telephone in power-dispatching work.

Some electric utilities have considered it desirable to provide facilities for communication along the transmission line right-of-way. Both portable telephone equipment and permanent stations installed at convenient locations have been used for this purpose. The accessibility of the transmission line and the relative importance of maintaining uninterrupted power service over a particular route determines whether or not such facilities are necessary. Apparently each situation requires individual study to ascertain its particular requirements.

In effecting centralized control of a power system, the value of telemetering, remote indicating, and supervisory-control services is gaining rapid and wide recognition. Where long distances are involved, apparatus operated by direct current over separate channels or by means of impulses sent over narrow frequency channels appears to be the most economical. For shorter hauls, the cost of conductors usually is not prohibitive, and apparatus using separate wires for each metering or control service probably is the most economical and desirable. Since normally, large investments in power equipment are involved, and manual assistance cannot be obtained quickly at unattended stations, the conductors used for control purposes must give reliable service.

In some of the larger electric systems, arrangements are desired which will permit the sharing of frequency control by several generating plants, or possibly in the ultimate provide for station load distribution on an automatic basis in direct proportion to the relative costs of generation. In this connection it has been suggested that for the purpose of synchronizing frequency-controlling devices in generating plants, a constant-frequency supply might be furnished over communication channels. For this purpose, apparatus employing a quartz-crystal oscillator in conjunction with vacuum-tube circuits is available in laboratory form; a frequency stability of approximately one part in ten million or about three seconds in one year is provided. Tests to determine the value of this constant-frequency supply in electric utility operation are being considered.

CUSTOMER SERVICE ACTIVITIES

A vital factor in supplying satisfactory electric service is the provision of convenient means for the customer to convey to the utility company his impressions and

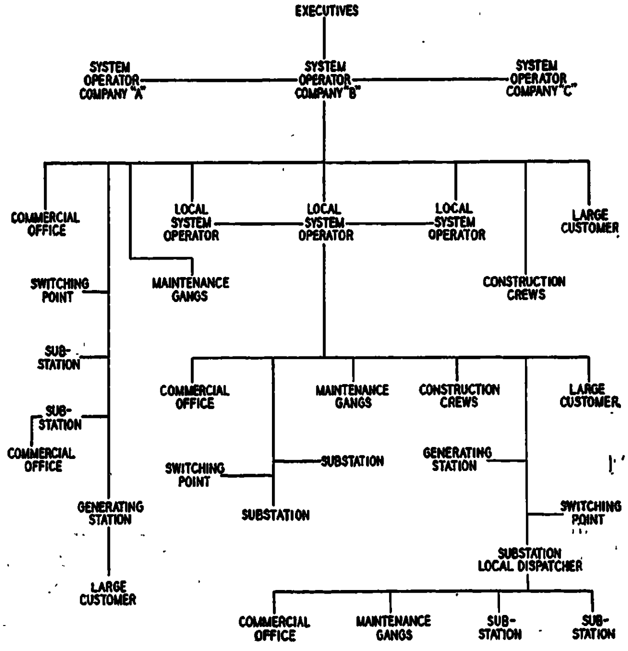

Fig. 1. Typical communication channels for perating activities of an electric utility

reactions regarding his electric service. Since a large majority of such contacts is made by telephone, electric utilities generally have recognized that customers calling by telephone should be handled as intelligently and as courteously as though calling in person.

Experience indicates the desirability of establishing an organization specially trained and assigned exclusively to dealing with customers over the telephone. Under this plan, direct observations can be made to determine which practises are most effective in building up good-will among the customers. Where centralized customer-service bureaus are established, communication channels are necessary between the bureau and the various departments in the company so that the attendants may obtain readily any information necessary for transacting business with customers. Usually the work of the bureau is simplified as much as possible; this may be done by providing a centralized file of customer records, by short-cut methods of handling customer orders, and by the convenient arrangement of telephone facilities.

ADMINISTRATIVE ACTIVITIES

Included in this group are executive, legal, engineering, and accounting matters together with certain features of operating work where speed of action is not the governing factor. The type and volume of administrative activity handled by telephone generally necessitates extensive circuit and equipment arrangements. These communication facilities usually are provided by the telephone companies. It is important that the electric utilities make their objectives clear so that the communication arrangements provided by the telephone companies will accomplish the desired results.

Essential requirements in communication channels for administrative traffic are no different than those for similar traffic in other lines of business. When the volume is sufficient, channels are leased for full-time use. Arrangements may be made with the telephone company also for short-period talking channels to be set up at certain specified hours of the day. Where traffic is light, ordinary public-message channels usually provide satisfactory service.

Where quick transmission of letters, orders, accounting matters, or other administrative affairs, is necessary, and a written record is desired, teletypewriter service has been found to be of particular value.

METHODS OF PROVIDING COMMUNICATION CHANNELS

Cable and open wire. Most of the communication channels used by electric utilities consist of cable and open-wire lines. Cable is relatively free from trouble during storms and is considered a desirable type of facility while from the standpoint of service continuity, open-wire channels are somewhat less desirable. Where open-wire circuits only are in use, enough channels often are available over regular or alternate routes to insure the desired reliability. Where necessary, extra guying, short spacing of poles, and similar measures are employed to strengthen such lines. There seems to be a growing disinclination, however, to rely upon open-wire facilities routed along the same right-of-way with power lines on which service is to be protected.

Carrier-current telephone apparatus. In a number of instances during storm breaks, power-line carrier-current equipment has provided the only means of communication available, and it is considered generally to be a reliable form of service. There appears to be a definite but somewhat limited application for this type of communication over long hauls where generating plants and substations in remote and sparsely settled locations must be reached. In such situations the cost of providing suitable cable or open-wire facilities may be prohibitive.

Variation in quality and volume of transmission often is experienced with carrier current due to the fact that the characteristics of the power network used as the transmitting medium are affected by switching or circuit changes. Difficulty also has been experienced in connecting the apparatus to two-wire circuits. Opinions as to the value of this type of equipment differ, and in order to arrive at satisfactory conclusions regarding the extent to which it logically may be employed, further experience is necessary.

Radio. In providing back-up service for regular communication facilities some use has been made of radio, but the cost of securing the desired reliability and restrictions as to operation have prevented any extensive use of this type of communication.

BASIC COMMUNICATION PLAN NEEDED

For most efficient results, maximum use should be made of all communication facilities, a satisfactory grade of service should be available for immediate use at the principal operating points, and future needs should be cared for slightly in advance of actual demand and without replacement of any large part of existing facilities. These objectives cannot be met economically without establishing a basic communication plan for the electric supply system as a whole, developed along consistent lines.

Extensive interchange of power between electric utilities and frequent consolidation of operating properties is emphasizing the need for some degree of uniformity in communication arrangements. Also traffic loads and operating contingencies usually can be cared for with a greater margin of safety and less expense where all telephone services and facilities are unified and operated as one system. Convenient switching arrangements accordingly have been developed to allow the operating department to seize quickly and hold any desired circuits for an indefinite period of time. These arrangements permit the exclusive use of circuits by the operating personnel whenever in their opinion such use is necessary, and would seem to provide in effect the equivalent of an exclusive communication network.

In a number of instances studies have indicated that best results could be secured through the connection of the electric utility's privately owned communication system to the facilities furnished by the telephone company. Interconnections of this nature enable the electric utility to eliminate all useless duplication of circuits and equipment, to obtain a broader use of privately owned plant, and to retire such plant investment in an orderly fashion.

Growth of the electric utility industry is extremely rapid. Activities of operating companies are broadening in scope continually as the areas served increase in size and customer demands become heavier and more exacting. It is important that the activities of electric utilities be studied constantly to determine how communication facilities can be used to greater advantage and to anticipate requirements so that the necessary service will be available when required. Consideration along these lines will assist to a marked degree in the attainment of that which utilities are striving for—continual improvement in customer service.

Communication in the Niagara Hudson System

By
E. S. BUNDY
Member A. I. E. E.

Buffalo (N. Y.) Niagara & Eastern Power Corp.

THE WESTERN DIVISION of the Niagara Hudson System which serves an area in New York State approximately 250 mi. long and 100 mi. wide has developed a coordinated communication plan including both privately owned and leased lines supplemented by carrier current. In the development of this system, engineers of the New York Telephone Company have worked in cooperation with the power company's operating and executive staffs to develop a flexible, dependable, and adequate communication network.

One of the outstanding features of this system is the manner in which customer calls are handled. These do not go to the general switchboard but are routed directly to a specially equipped order receiving table where a specially trained personnel handle them directly without irritating department-to-department transfers.

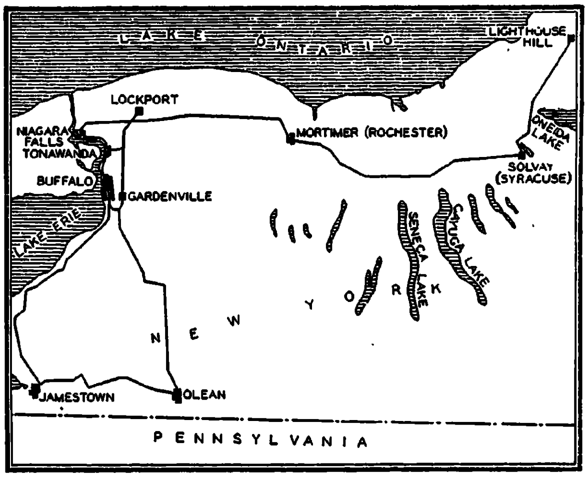

Fig. 2. Transmission system of the Buffalo, Niagara & Eastern Power Corporation (western division) showing principal switching points

Lines leased from the telephone company for full 24-hr. use connect the load supervisor (at Buffalo) with the Buffalo steam stations, the Niagara Falls hydro station, and the Lockport switching station, these being key points on the transmission system. Three of these leased lines provide remote-metering facilities for indicating at a glance the total load on the 60- and 25-cycle steam stations in Buffalo, and the hydro station in Niagara Falls, these being the three main power sources for the western division. Provision is made also for reaching Mortimer, Lyons, Solvay, and Syracuse through Lockport, and Gardenville, Jamestown, and Olean through the automatic dial-switching equipment in the Buffalo office. (See Fig. 2.)

In addition to the foregoing facilities the four main switching stations of the division, Niagara Falls, Lockport, Gardenville, and the Buffalo steam stations, are tied together directly by leased lines, so that district load supervisors may hold from two- to four-party conversations for discussing the proper execution of orders. The load supervisor's office is equipped with cordless turrets (similar to that shown in Fig. 5) for the interconnection of telephone lines of all types and for the quick and easy answering and switching of calls.

Among the many advantages of leased lines are these; that they do not follow the transmission right-of-way, and where two leased lines are in use between important points, they follow different routes. Both of these features enhance the inherent reliability of these lines. In addition, during storms the first responsibility of the power company is to maintain the transmission lines; where leased lines are used, the telephone company handles the communication problem. The possibility of storm failure is reduced to a

---

minimum, however, because practically all leased lines are run in cables.

Although the company is a large user of leased lines, thus eliminating maintenance worries and profiting from the advice of experts in the field of communication, privately owned lines belonging to predecessors are used where they were found to be in good condition. These private lines are interconnected with the leased lines, suitable protective equipment being installed at the connecting points. Such an arrangement provides great flexibility in the communication system and makes possible the use of previous investment in privately owned lines.

Eight carrier-current stations are maintained at main switching points, but under normal conditions these are not used to any great extent where leased lines are available; however, to make sure that it is in operating condition for possible emergency use each set is tested daily.

INTERDEPARTMENTAL COMMUNICATION

In the company's branch exchange in Buffalo, and in several of the district offices, machine switching equipment has been installed. Calls from one department to another are dialed by the calling party directly, as are calls to the telephone company's central office. Operators on general office switchboards thus handle only incoming calls to that office. As a result, calls have been speeded up and in the Buffalo office the staff of operators has been reduced from nine to five, despite the fact that telephones served have increased in number from 189 to 325, with a corresponding increase in the amount of traffic handled.

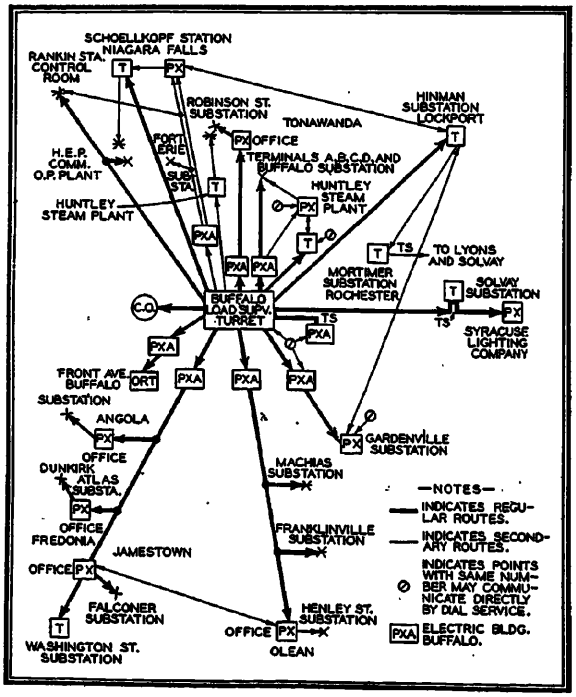

Fig. 3. Diagram of load dispatcher's communication facilities

In some of the smaller district offices, normal traffic will not justify the installation of machine switching equipment but service to customers, especially during times of trouble, will. In such cases operating men must be able to reach all parts of the system without interference from incoming calls. Where the dial system has been installed, the operating men can call the stations directly; a flood of customer calls thus does not interfere with their activities, and, at the same time, the telephone operator can devote undivided attention to customers.

CUSTOMERS' CALLS

Telephone calls from customers do not go to the general office switchboards but are routed directly to specially equipped order receiving tables. In the Buffalo office eighteen special trunks connect from the telephone company's central office to this table, and these are arranged in such a way that any call may be taken at any one of three different positions, there being a total of fourteen positions at the table.

Specially trained young women handle all types of these customer calls, which are largely reports of trouble, requests for service connections or disconnections, complaints, and requests for information. All positions at the table are connected by direct lines with the meter and trouble departments. Also ten tie lines connect the table with the company's machine switching equipment, thus allowing for connections to any one of the 325 extensions on this branch exchange.

Numbers are so listed in the telephone directory that customers rarely call the general office switchboard by mistake. When these errors do occur, however, they are connected by the telephone operator to the order receiving table without inconvenience and without being required to make a second explanation of what they want. Customers' calls which come to the service department but which really should go to the general office switchboard receive the same attention.

To maintain proper supervision over the telephone contacts with customers and at the same time bring about improvements in telephone usage, a monitor set has been installed so that observers may listen in on all conversations through the company's private branch exchange. Conversations are taken down verbatim and subsequently discussed at departmental meetings.

Five telephone typewriters connect this department with the meter and trouble departments located in the service building two miles distant. These teletypewriters are operated over leased lines and provide filled-in order forms on both the sending and receiving machines, the entire operation being completed within a very few minutes after the customer's request has been received.

Telephone contact with customers thus has been centralized in a well-trained department with great improvement in public relations. The personnel of the department follows through each request to completion; and moreover the customer is not transferred, disappointed, or kept waiting.

SUMMARY

The principal features of special interest in the communication scheme of this system briefly are that:

1. The company relies largely upon advice of the telephone company's engineers, believing that they are the best authorities available in the communication field.
2. Leased lined are used chiefly, thus freeing the company of maintenance problems and providing better and more dependable voice transmission.
3. Wherever practicable, automatic equipment is used for speedier service.
4. Both leased and private lines are interconnected for maximum flexibility.
5. In the interest of better public relations, great care has been taken to insure that customers' calls receive the best and most courteous service.

Joint Study Improves Communication Facilities

By
C. A. BOOKER New England Pwr. Assn., Boston, Mass.

M. E. CLARK New England Tel. & Tel. Co., Boston, Mass.

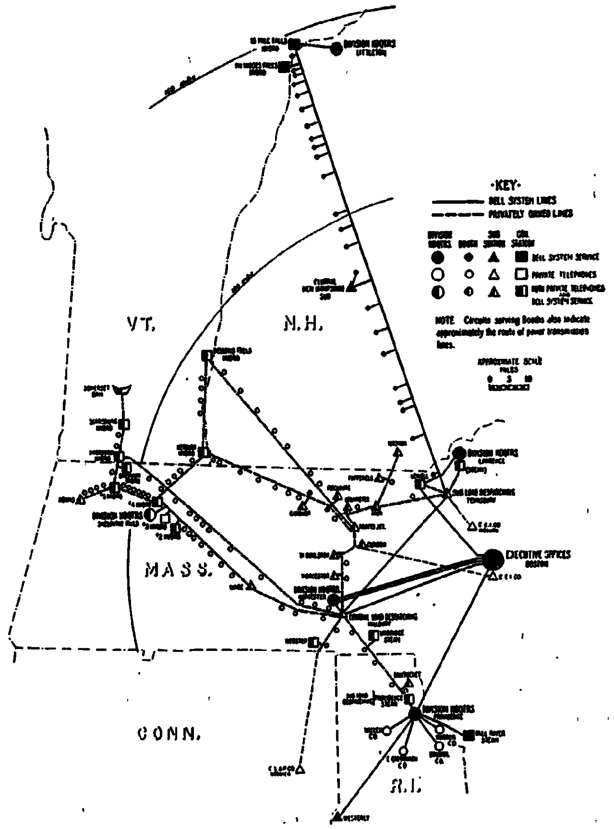

Fig. 4. Principal communication circuits of the New England Power Association

A LARGE GROUP of interconnected wholesale and retail electric companies are operated by the New England Power Association in a highly developed industrial area covering parts of five states. Energy is generated at eleven major hydro stations on the Connecticut and Deerfield rivers, whence it is transmitted over a high-voltage network to the load centers in central and eastern Massachusetts and Rhode Island; here interconnections are made with several large steam generating plants. To insure maximum economy in operation, a centralized control over all producing and distributing units is necessary.

To maintain this centralized plan of control, a network of communication circuits consisting of lines leased from the Bell telephone system interconnected with privately-owned lines has been set up (see Fig. 4). This arrangement represents the results of a joint study by executives of the telephone and power companies, instituted several years ago when the need for a more closely coordinated communication system was felt.

Operating control over the entire system is exercised by the load-dispatching department. This department has jurisdiction over power production, apparatus, safety work, the scheduling of future operations, and arrangements for power interchange with other systems. Control operations are planned from an extensive system of hourly reports received from each producing and distributing unit. Most of this work is carried on over approximately 600 mi. of privately owned telephone circuits.

For customer service and other commercial relations, regular subscriber service of the Bell system is used. Where the volume of traffic warrants it, P. B. X. (private branch exchange) switchboards are installed. Telephone extensions to the customers' service department are so arranged that all calls involving service on anything from flat irons to electric refrigerators are received at one place. This is done in order that such calls may receive prompt and sympathetic treatment without irritating transfers from one department to another.

Administrative activities of all units in the entire system are carried on from central offices located at Boston over a coordinated network of leased lines. By

interconnections at territorial office switchboards, economical and speedy communication with every part of the system is provided.

JOINT STUDY CONDUCTED

The joint study between telephone and power company engineers mentioned previously was instigated in 1929, when, with the consolidation of all of the principal offices at Boston, it became urgent to improve all types of service. In this study the entire communication problem was analyzed by parties having a thorough knowledge of modern telephone equipment, in cooperation with those most familiar with the operation and needs of the power system. Activities of the group conducting the joint study may be classified briefly as (1) a complete survey of existing communication facilities and usage; (2) the determination of present and future requirements; and (3) the analysis of these requirements to determine what alterations or additions are needed.

RESULTS OF STUDY

Although the survey has not been completed, many improvements in communication service already have resulted. Private branch exchanges serving local areas, districts, and divisions have been rearranged and in some cases modified to meet more fully the requirements of the territory served. In some instances these modifications have been effected at an actual saving in cost. Some of the more important findings of the joint study are outlined in some detail in the paragraphs which follow.

One of the earlier determinations of the joint study was the need for better call-handling facilities in the load dispatcher's office. It was desired to provide access to all lines but with a minimum of switching by the dispatcher. This was accomplished by the use of cordless turrets placed adjacent to the dispatcher's desk (see Fig. 5). The circuits were arranged so that the P. B. X. operator handles all calls not intended for the dispatcher, but at the same time the dispatchers have full control of all lines for possible emergency use. Provision is made for visible as well as audible indication of incoming calls.

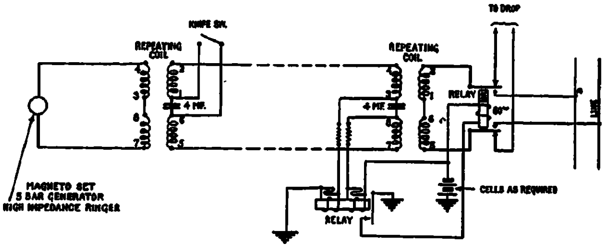

Fig. 6. Schematic diagram of patrolman's spur lines along the Tewksbury-Fifteen Mil Falls transmission line

Another noteworthy result of the study is found in the reduction of noise on the company's privately owned lines. This was brought about by a complete field inspection and survey followed by the correction of transposition unbalances, clearing up of tree troubles, and the replacement of broken insulators and bad splices, wherever the survey indicated that these steps were necessary.

Advantages of the joint survey for determining future requirements were realized in the planning of communication facilities for the Fifteen Mile Falls hydro development in 1929. The final arrangements for this particular case consisted of leasing a line from the Bell system from Tewksbury to Fifteen Mile Falls (see Fig. 4) with a permanently bridged tap to the central New Hampshire substation. This decision was reached when it was considered that (1) in case of trouble the telephone company could furnish duplicate paths, (2) within a few years the entire line would be of so-called sleet-proof construction, and (3) that the annual cost to the power company would be lower than the cost of constructing and maintaining a privately owned line.

A novel feature of this particular line is the arrangement for communication facilities from patrol booths along the line (see Fig. 6). These facilities are provided by spur lines having an average length of about five miles, and extending from the booths to central offices through which the main line passes. These extensions normally are disconnected from the trunk circuit, but each line may be connected by simply closing a switch in the booth, the actual connection being made by a relay. Provision also is made to enable the patrol station to signal the operator at the telephone company's central office in case exchange or toll service is desired.

Special arrangements have been made by the telephone company for routine and emergency maintenance of this line, and if for any reason the leased line is out of order preferential treatment is guaranteed for dispatching business over regular toll circuits.

CONCLUSIONS

Although the communication requirements of the New England Power Association have presented some unusual problems, joint consideration of these requirements has resulted in a satisfactory communication system. The provision of adequate communication service is essential to the operation of the power company, and in order that this may be accomplished economically and with minimum duplication of effort, as the requirements change in the future it is planned to continue the joint survey work.

Communication in a Metropolitan System

By
P. B. JUHNKE
Member A. I. E. E.
Commonwealth Edison Company, Chicago

COMMUNICATION facilities for the Commonwealth Edison Company system (Chicago) the fixed plant of which is scattered over the entire city, include 19 telephone switchboards, and a total of about 2,600 telephone stations. The main switchboard, together with seven sub-boards, are located in the Edison Building in the downtown section of the city. Of particular interest are the facilities employed in the technical direction and supervision over operating activities.

Operation of this system is carried on like most other large systems by a specially trained technical group located in a central load-dispatching office. Direct private-wire connections are provided between this office and all generating and distributing stations and the majority of substations. Dispatching activities are subdivided into three sections, two of them dealing with the usual routine of load dispatching, and each having supervision over a certain part of the system. The third division known as the load-control section is of relatively recent origin and is charged with supervision over the supply of power from the different generating centers. This third section also has supervision over the 66- and 132-kv. tie-line elements between stations. These supervisory activities embrace not only generating stations and tie lines within city limits but also interconnections with, and supply from, generating stations outside of the city. Direct telephone communication is provided from the load-control group's own two-position board to all generating stations and 66-kv. switching centers.

Before the organization of the load-control section, its functions were carried on by the load dispatchers making this work part of their regular duties. When only two or three generating stations were in operation the load-division problem was fairly simple, but as other stations were added to the system, each in turn more efficient than its predecessor, this problem became more complex. Accordingly a system was set up whereby the load distribution was adjusted hourly on the basis of corresponding hourly load readings from the individual stations. Although this scheme worked out very well, it required almost continuous readings to distribute the load properly, and as more generating stations were added to the system it became quite a laborious process.

LOAD-TOTALIZING SCHEME

As an outcome of the hourly system of load apportionment, a load-totalizer was developed to collect the individual station loads in the dispatcher's office, the power reading being transmitted by remote metering over telephone wires. Although this original arrangement represented a definite step forward, continuous direction on the part of the dispatching personnel was required to maintain the proper load apportionment. Accordingly, this original scheme was followed by further development known as the load-totalizing scheme with reverse indication. In this latter plan the totalization indications effected in the load dispatcher's office are transmitted back to the individual stations. With the aid of these continuous total-system-load readings and previously prepared load charts, each operator can hold the load on his particular station to its proper value at all times.

REMOTE-METERING SYSTEM

The remote-metering system used in totalizing the station loads has been described in a previous publication. ("Budget-Plant Load Dispatching," by P. B. Juhnke and L. N. Moore, *Electrical World*, Vol. 89, pp. 1317-1320.) However, a number of improvements recently have been made in this apparatus. Instead of balancing the effect of the impulses by mechanical means as done originally, some of the recorders have been changed to operate on a resistance bridge arrange-

---

From "Communication Facilities of a Metropolitan Power System" (No. 31-98) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

ment. With this improvement it is not necessary to install all of the meter elements on the load dispatcher's board. Several load recorders thus can be mounted in a relatively small space so as to be easily read by the personnel at the load-control board. Since all of the charts are controlled by the same synchronous motor, records may be compared directly and all meters will record for the correct time.

Metallic telephone circuits are used exclusively in this remote-metering scheme as installed by the Commonwealth Edison Company. However, the impulses (into which the load readings are translated) can be transmitted by means of carrier current,—a feature which materially enhances the usefulness of the system, especially for metering distant stations.

This type of installation is believed by the author to make possible the most intelligent operation of a large interconnected system. The task of directing load-scheduling activities is continuous and practically automatic. In addition, the economies gained in plant operation of a system of moderate geographic extent more than warrant the cost of the equipment and incidental telephone line rental.

Carrier Communication Economical for Long Distances

By

E. C. STEWART

Arkansas Pwr. & Lt. Co., Pine Bluff

CARRIER-CURRENT telephony supplies most of the communication needs for the Arkansas-Louisiana-Mississippi interconnected system comprising a total of approximately 1,800 mi. of 110-kv. lines. Operating supervision for the entire interconnected network is centered in the load-dispatcher's office at the Woodward switching station near Pine Bluff (Ark.) except for the southern portion which is handled from the Jackson (Miss.) office. (See Fig. 8.)

Upon completion of Remmel Dam near Malvern (Ark.) in the latter part of 1924, and the connection of the hydro plant at that location with Pine Bluff and Little Rock, an urgent need for fast and reliable communication was felt. The construction of a new communication line along the power line right-of-way was contemplated but it was believed to represent an unwarranted expense when the reliability of such a line was compared with that of the power line itself. Finally, after a careful consideration of these and other factors involved, carrier-current equipment was installed during the early part of 1925. Results with this first installation were so satisfactory that in 1926 when the communication service had to be extended to Sterlington (La.) additional carrier-current equipment was used for this purpose.

Further extensions of this transmission system have necessitated corresponding extensions in the communication system; these likewise have consisted of carrier-current applications. At the present time a total of eleven carrier-current installations has been made located as shown in Fig. 8. In most cases comparatively long transmitting distances are involved, the longest of these being the 459-mi. stretch from Pine Bluff to Gretna.

To prevent the carrier waves from being dissipated on portions of the transmission system not used for communication purposes, by-passing and frequency-blocking equipment is installed at some locations. Arrangement of this equipment as installed at the Woodward switching station is shown in Fig. 9. Two transmitting sets are in use at that station so that additional blocking had to be employed.

Carrier-current equipment of the Southwestern Gas & Electric Company, shown also in Fig. 8, operates on a

---

From "Communication on the Arkansas-Louisiana-Mississippi Interconnected System" (No. 31-116) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

frequency channel different from that of the Arkansas-Louisiana-Mississippi interconnection, but so far no frequency blocking has been found necessary between the two systems. For communication between the two systems separate receivers are employed at Pine Bluff and Shreveport.

With the exception of the Remmel Dam set, where antennas are used, all coupling between the carrier-current apparatus and the transmission lines is by means of capacitors. No failures have occurred on any of these units during the past two years, which is the maximum length of time that any of them have been installed.

OPERATION

The carrier-current installations on the interconnected system, supplemented by the use of toll service and one or two leased lines, are primarily for use by the dispatcher. A certain amount of business traffic is handled, however, outside of rush periods, and is relayed by the dispatchers to the parties addressed.

Records of the number of messages transmitted show that at the Woodward station the average number of carrier-current equipment operations per month is about 4,800 for both installations. A three months' study of the time of usage indicates that the average message length is only 1¼ min.

Direct communication between outlying stations on the interconnected system has not been allowed because there is little advantage in this from a system operating standpoint. Calls of this nature are handled through the Pine Bluff dispatcher, his office having been made a "central" for that purpose. To complete such a call, it is necessary for the substation instigating the call to signal the Pine Bluff dispatcher from whence the call is dialed to the station desired. Completion of the call is evidenced by the automatic starting up of the transmitter at the station called.

Up to the present time carrier current has not been provided along the lines for the use of patrol or maintenance men. Routine patrolling reports are not turned in by telephone except under emergency conditions when the nearest available form of communication is utilized. During the past three or four years whenever weather conditions have permitted emergency patrolling has been made by means of airplane. Reports of

observations made in this way usually are dropped in pasteboard containers to a substation operator, who relays the information to the dispatcher. In these reports, exact structure numbers are given in order to fix definitely the location of the trouble. Identification is made by means of distinguishing markers on top of key structures which are readily visible from the plane.

RELIABILITY

A number of instances are on record showing that the carrier-current type of communication affords an extremely reliable type of service. Several times during storms when other means of communication were disabled, uninterrupted service was maintained over the carrier-current circuits. One instance of particular note occurred during the months of April and May, 1927, while the Mississippi Valley was engulfed in the great flood of that period. For many days carrier current provided the only means of communication to the Sterlington station.

The Way to Progress and Prosperity

Equitable taxes and fair distribution of the cost of government in place of the present unfair indirect bonus system is urged as a vital first step toward cultural progress and public welfare. This is the third article of The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"

By
C. E. GRUNSKY President, American Engineering Council

UNEMPLOYMENT is the most striking symptom of recurrent hard times. Attribute this, if you wish, to the fact that one man now produces what three or more could produce a few years ago, but remember that demand in kind and quantity also has increased vastly. Depressions would be recurrent even if the typewriter, the harvester, and the automobile had not been invented. However, the relative number of basic producers has been materially decreased and, in consequence, increasing numbers must be provided with occupation in distribution, cultural activities, and recreation.

Opportunity to work should be provided for every person dependent upon his own efforts. Obviously this opportunity cannot be supplied at the bottom of the scale of human endeavor, else over-production would result. But, there is always room at the top. The great need is for a stabilizer, in the form of activities disconnected from the production of material necessities, which will provide in every country a steady flow of money from hand to hand. This stabilizer is close at hand. It will not prevent, but it will mitigate recurrent business depressions.

The nation's spiritual and cultural advancement are of greater importance than provision for material well-being. Expenditures of public funds for such purposes comparable with those for the safeguarding of life and property, for the protection of health, and for facilitating the exchange of products would not be unreasonable, but there is fear of the tax burden. Under a well balanced program the nation should get vastly more scientific research, expansion of educational opportunity, and encouragement of art. Education and art advancement should be provided for in all centers of population, by the erection of monuments, the establishment of museums, art galleries, and conservatories of music, and by the maintenance of opera houses with opera companies. These expenditures would contribute to the spiritual uplift of the people and to the progress of civilization. Provision for outdoor recreation should be made throughout the land on a scale never yet approached. Lands should be reserved and acquired so that those who go into the open may find suitable places to picnic and to camp. During periods of declining prices there also should be a speeding up of public works, on a sane program. Recourse to pick and shovel, instead of modern appliances, is but a trifle above giving a dole with its encouragement of idleness and of return to primitive conditions.

The basis of such a program of course is a high rate of taxation, and any suggestion that the government spend more money, particularly in business depressions, is commonly frowned down. The fact is ignored that when capitalists close their purses, government must spend to avert disaster. Objection should not be to the magnitude of the sum to be raised, but to the prevailing unfair systems of apportioning the tax. If the burden were distributed commensurately with ability to pay, there would be less dissatisfaction and the public soon would learn that the greater the tax the less the slump in the aggregate volume of the country's business.

Tax money thus put into circulation would create a volume of business that readily could bear the tax from year to year. To make this clear, let it be supposed that times are hard, money scarce, and that Jones has run up a bill of $100 at the grocers. The grocer has gone into debt to a truck gardener in the same amount; the truck gardener owes the butcher $100; the butcher owes the baker; the baker owes the plumber; and so on 100 times creating a total indebtedness of $10,000 with 100 persons complaining of the difficulty of making collections. Jones finds employment and pays his grocery bill. The grocer pays the truck gardener with the $100 received from Jones and so on until a single $100 in a few days may have reduced outstanding indebtedness by $10,000. The dollar started keeps on going from person to person normally from 30 to 50 times in a year, until hoarded somewhere or until its speed is checked during some business depression. If money received from equitably levied taxation is spent economically at home it will, in passing from hand to hand, create business in the long run for each taxpayer in substantially the proportion in which he has contributed. Each dollar thus expended by the government should create from 30 to 50 dollars of business in a year with, of course, some annual shrinkage. There appears no reason, in theory, why taxes should not be welcomed.

Much unproductive property, such as furniture and works of art, is too heavily taxed. So also is real estate. Why tax the goods or the material which the merchant or manufacturer has in stock when his business is "in the red"? They should pay something for the privilege of doing business, based upon the volume of business, and they should contribute to the government a part of the net profits. The tax on real estate should be just enough to prevent the land from lying idle too long. The main guide in fixing the individual's tax should be ability to pay, that is to say, his net income. Taxes should be graded and there might well be a minimum below which there would be no taxes.

Indirect bonuses have increased the tax burden of those who do not get such bonuses. The veteran is granted tax exemption, amounting in some states to $1,000, an indirect bonus perhaps equivalent to $40 or $50 per year. Such exemption has almost universal approval. However, another veteran of necessity living in rented quarters with wife and children, and who therefore cannot benefit from the exemption, does not get the indirect bonus for which he probably is in much greater need. The exemption is unfair; every such bonus should be direct, not indirect.

Salaries of public employees and officials are tax free—equivalent to an addition to the individual's earnings—an indirect bonus automatically largest for those with largest incomes who best could afford to pay an income tax. Earned incomes are exempted from the federal base tax to an extent of 25 per cent. An indirect bonus equivalent to the tax on $1,250 thus is given to the man who has a salary of $5,000. His neighbor whose earned income is $30,000 obtains an indirect bonus *six times as great*, yet the latter is in better position to pay. Scientific, religious, and like institutions are exempted, equivalent to giving a bonus. To the extent of the aggregate indirect bonuses thus granted, the other tax payers carry a heavier burden.

Government, state, and municipal bonds are tax free, supposedly for advantage to the public on the basis that they thus become marketable at lower rates of interest—only a fancied advantage that may lead to injustice. All the bonds issued by one municipality may be held by residents of another. In the second city a corresponding amount of property is taken off the tax list, with the result that all other property is more heavily taxed. The increased burden thus results in advantage to the residents of another municipality. If all bonds issued by a municipality are owned by residents of that municipality, the tax rate on the remaining property must go up in an amount that will more than offset the advantage which results from the low interest rate at which the bonds were issued. If the holder of the bonds did not profit by the tax exemption, the low interest rate bonds would not be attractive—another indirect bonus.

When the Panama Canal was constructed bonds for nearly $400,000,000 were issued. These bonds went into the hands of bankers who deposited them in the United States Treasury for the privilege of issuing bank notes secured by these bonds. The bank notes, which may have approximated 90 per cent of the amount of outstanding bonds, went into circulation as currency, the banks thus being permitted to borrow from the public, at a small engraving cost and a moderate tax, hundreds of millions of dollars without paying interest—an indirect bonus.

Under the Reclamation Act of 1902, and its amendments, the settler is required to pay back to the government within 40 years the cost of the irrigation works, but without interest—an indirect bonus practically equivalent to the cost of the works. If constructed privately the works would have cost the settler twice as much.

Several cities in Kansas have no taxes, a situation welcomed by all. The cost of government has been shifted from the tax payer to the rate payer in water, light and power bills, and car-fares. The public utilities are owned by the municipalities and the profits are sufficient to meet the budget requirements. By this arrangement the *wealthy* have been *relieved of their just share* in the cost of government at the expense of those in moderate circumstances. Real estate owners and capitalists are presented with an indirect bonus.

Other illustrations could be given to indicate how general these indirect bonuses have become.

Equitable taxes and fair distribution of the cost of government is the first step to the expansion of activities for cultural progress and public welfare as a means of preventing extreme distress during business depressions.

Editor's Note: Pursuant to the invitation of The Engineering Foundation, the editors will be happy to receive comments, suggestions, criticisms, or discussions pertaining to this or the other articles published in this series.

The Simplex Synchronous Motor

Salient-pole synchronous motors with phase-connected damper windings are capable of developing high starting and pull-in torques with low starting current, as revealed by information given here.

By
M. A. HYDE, JR.
Associate A. I. E. E.
Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

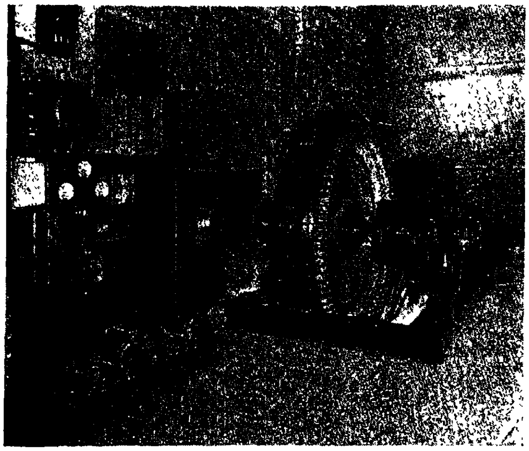

Fig. 1. A 300-hp. 164-r. p. m. synchronous motor of the phase-connected damper type and with associated control serving a cement plant

NOTEWORTHY PROGRESS has been made during recent years in the application of low-speed synchronous motors to industrial loads requiring both high starting and pull-in torques with moderate starting-current demand. The problems encountered are exemplified in the drive of grinding machinery in the cement and mining industries. There has been built for this type of service a form of salient-pole synchronous motor which develops these characteristics electrically without the use of any mechanical clutch or other loading device, and in a manner resembling the starting characteristic of the slip-ring induction motor.

Tests on machines of this type have shown starting torques in the order of 200 per cent of full-load torque, pull-in torques of 120 per cent and more, and starting-torque-per kva. ratios of from 0.6 to 0.7,

The construction is basically that of a two-bearing, coupled, salient-pole machine with certain deviations from the hitherto usual form. Instead of the ordinary cage form of damper winding this motor employs a damper winding consisting, as usual, of a single bar per slot in the pole face; but these bars are of low resistance copper and are connected to form a polyphase winding similar to the secondary winding of a slip-ring induction motor. This construction is shown in Fig. 2. The damper winding is connected through three slip-rings to an external grid-type starting resistor. In starting, this resistor is cut out in steps by the control as is done in starting a slip-ring induction motor and the damper winding circuit thus is given a succession of decreasing resistance values, providing advantageous speed-torque characteristics throughout the accelerating period.

It may be noticed in the rotor illustrated that the pole faces are comparatively broad, permitting the damper winding to occupy a large portion of the pole pitch and to be favorably distributed from the standpoint of phase balance. To avoid the high eddy currents normally present during starting in the usual solid rotor rim, the rim of this machine is laminated.

The motor is started with field open-circuited; this eliminates the low-power-factor current that ordinarily circulates in the field when closed on a resistor at start, as commonly is done. The disadvantage generally resulting from open-field starting is the high transformer voltage on the field winding at start, and to obviate this several motors of the type described have been constructed with field designed for low-voltage excitation. These proportions involve higher excitation and fewer field turns, the latter resulting in lower transformer voltage on the field winding. A 1,000-hp., 1,800-r. p. m. 100 per cent power-factor motor constructed for low-voltage excitation required 8 kw. at 45 volts direct current, and developed at standstill by transformer action 3,300 volts across the field terminals. This voltage diminishes to zero as the rotor accelerates to synchronism.

Since the transformer voltage on the field at start is proportional to the number of field turns in series, the practise of field sectionalizing may be used. After extensive shop and service tests some motors have been built in which a centrifugally-operated sectionalizing switch is employed to break up the field into sections at start and to connect the sections in series after acceleration to a predetermined speed, when the transformer voltage is correspondingly reduced. A 300-hp., 164-r. p. m., 100 per cent power-factor motor employing such a switch and with a field designed for 125-volt excitation developed about 3,000 volts per section. The switch is built as a unit enclosed in a tight housing

---

From "The Synchronous Motor with Phase-Connected Damper Winding for High-Torque Loads," (No. 31-43) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

and mounted within the rotor. Close scrutiny will discern one of these switches in the rotor of Fig. 2.

Control equipment employed with these motors is of magnetic definite-time-sequence type; its operation is explained by Fig. 3. In the control diagram the field is shown separated into three sections at standstill by the sectionalizing switch *F S*. In starting, the spring-closed auxiliary field switch *F*-1 is opened first; then the stator is connected to the a-c. supply with full starting resistance in the damper circuit. This resistance is shunted in steps by the closing of *S*-1, *S*-2, and *S*-3, and the motor accelerates along the corresponding speed-torque curves R_1, R_2, R_3, and R_0. Next the auxiliary-field switch *F*-1 is closed and the field, now connected to the field resistor, increases the induction-motor torque along curve R_{OF}. Finally d-c. excitation is applied by contactor *F*-2 and the motor synchronizes, operating thereafter as an ordinary salient-pole machine. In stopping, the centrifugal sectionalizing switch remains closed until a low speed is reached, permitting the field switch *F*-2 to be opened previously and a discharge circuit through the field resistor established. The control is arranged to prevent starting the motor with the field sectionalizing switch in the closed position. The auxiliary field switch is used to separate the field terminals from the control apparatus during starting, employing for this service a spring-closed contactor which ordinarily is mounted on a covered panel at the rear of the main panel.

The tabulation of starting performance given in Table I shows test results attained with several representative ratings during the development of this equipment. The starting-torque kva. ratios of 0.6 and 0.7 are about twice the values considered good for low-speed synchronous motors of ordinary construction when designed for similar torques.

It is interesting to compare this motor with the ordinary compressor motor. With a current inrush of 275 per cent the standard compressor motor torques are 50 per cent starting and 40 per cent pull-in, whereas the simplex motor delivers with this same starting current a starting torque of 150 per cent and a pull-in torque of 120 per cent. This high starting performance is obtained without sacrifice of efficiency, with excitation characteristics suited to commercial d-c. voltages, and with starting torque adjustable in value to suit the needs of the installation.

Table I—Simplex Motor Starting Performance

Hp. rating	1,000	300	300	350
Speed in r. p. m.	180	164	164	400
Power factor, per cent	100	100	100	80

Stabilization of Industry

Details are discussed of a plan which would provide for the regulation of industry through mutual trade associations under federal supervision. Production, consumption, and other factors would be coordinated to reduce cyclic variations; employees would participate jointly in providing unemployment insurance protection and other benefits which would accumulate for the employee regardless of legitimate changes in company or industry affiliations.

By
GERARD SWOPE
Fellow A. I. E. E.

President
General Electric Company

IN THE SITUATION that confronts us at the present, the most disturbing aspect is that men who are able to work, who are competent workers, who, above all things desire to work, cannot find work to do. That this condition ever has been present in such periods detracts nothing from its wrongness. That industry must evolve and make effective those measures which first will ameliorate, and ultimately eliminate it, must be the reaction of everyone who gives thought to what is taking place. I say that industry must do this thing, because surely it will be done.

Benefits earned by a worker in one employment are wholly or in large measure lost by forced changes; or the right of choice of employment, which should be inalienable, is hampered. From the operation of individual life insurance and pension systems, however well conceived, has arisen the complaint of the "forty-year dead line," which it is claimed has seriously affected the ability of men exceeding that age to find new employment. Wide application is essential if benefits gained in one location are to follow the worker as necessity may indicate change of location, and this is a vital factor of any plan which will meet the need. If there were provided in the United States a system of benefits accruing through the life of the worker and following him wherever he might go, from shop to shop within a particular industry, or from branch to branch within industry as a whole, such provision would enlist, not merely interest on the part of the worker, but enthusiastic support.

PRODUCTION AND CONSUMPTION MUST BE COÖRDINATED

Industry exists basically for serving the needs of the people, and therefore production and consumption must be coordinated. Consumption is by the mass of the population, not the few, and the great mass of the population is made up of wage earners and their dependents. That they may be able to buy and satisfy their needs, they must have not only adequate incomes but must be sufficiently assured of the future to feel that they are safe in spending their money. The psychology of fear must be removed; and this cannot be done unless they have reasonable expectation of protection for their families in case of the breadwinner's death, protection for their old age, and protection against unemployment. By "protection" I do not mean a protection that is given to them, but I mean protection that they themselves help to provide.

Shall we wait for society to act through its legislatures, or shall industry recognize its obligation to its employees and to the public and undertake the task? Coordination of production is impossible under our present laws, and it is vain to think of their amendment or repeal unless the public is assured of the constructive nature of the steps industry will take, and that the interests of the public will be adequately safeguarded.

UNDERLYING PRINCIPLES

The general principles underlying what I am going to say are as follows:

1. Every effort should be made to stabilize industry and thereby stabilize employment to give to the worker regularity and continuity of employment; and when this is impracticable, unemployment insurance should be provided.

2. Organized industry should take the lead, recognizing its responsibility to its employees, to the public, and to its stockholders—rather than that democratic society should act through its government. If the various states act, industry will be confronted with different solutions, lacking uniformity and imposing varying burdens, making competition on a national scale difficult. If either the individual states or the federal government act, the power of taxation has no economic restraints.

3. There should be standardized forms of reports so that stockholders may be properly informed. As a result of the steady increase in number and size of corporations and number of shareholders, there has been much discussion of the uniformity, frequency, and regularity of reports of corporate activities, and considerable criticism of the form of these reports. Some are too conservative, some not sufficiently complete, while others are considered to be fair and complete. There is a lack of uniformity among the different companies.

4. Production and consumption should be coordinated on a broader and more intelligent basis thus tending to regularize employment and thereby removing fear from the minds of the workers as to continuity of employment, as to their surviving dependents in case of death, and as to old age. This should be done preferably by the joint participation and joint administra-

---

An address delivered before the National Electrical Manufacturers Association at the Hotel Commodore, New York, N. Y., Sept. 16, 1931.

tion of management and employees. These things cannot be done by an individual unit—organized industry must do them.

5. If organized industry is to undertake this work, every effort should be made to preserve the benefits of individual originality, initiative, and enterprise, and to see that the public is assured that its interests will be protected. This can be done most effectively by working through the agency of the federal government.

There is nothing new or original in what I am proposing. I am merely bringing together well-considered propositions that have found support, including some that have been put into actual practise.

The following plan is offered as a means to correlate into a comprehensive whole the present undirected efforts of forward-looking business enterprises toward stabilization (1) for the further development of industry and commerce, (2) for the protection of employees and stockholders, (3) for the best service to the public, and (4) in general for the best interests of society. Legislation will be required to make such a plan possible, including the probable modification of some existing laws.

Trade Associations the Answer

An outline of the more important features of a possible "industrial constitution" is given in the following paragraphs:

1. All industrial and commercial companies (including subsidiaries) with 50 or more employees, and doing an interstate business, may form a trade association which shall be under the supervision of a federal body referred to later.

2. These trade associations may outline trade practises, business ethics, methods of standard accounting and cost practise, standard forms of balance sheet and earnings statement, etc., and may collect and distribute information on volume of business transacted, inventories of merchandise on hand, simplification and standardization of products, stabilization of prices, and all matters which may arise from time to time relating to the growth and development of industry and commerce in order to promote stabilization of employment and give the best service to the public. Much of this sort of exchange of information and data already is being carried on by trade associatons now in existence. A great deal more valuable work of this character is possible.

3. The public interest shall be protected by the supervision of companies and trade associations by the Federal Trade Commission or by a bureau of the Department of Commerce or by some federal supervisory body specially constituted.

4. All companies within the scope of this plan shall be required to adopt standard accounting and cost systems and standardized forms of balance sheet and earnings statement. These systems and forms may differ for the different industries, but will follow a uniform plan for each industry as adopted by the trade association and approved by the federal supervisory body.

5. All companies with participants or stockholders numbering 25 or more, and living in more than one state, shall send to its participants or stockholders and to the supervisory body at least once each quarter and in the prescribed form a statement of their business and earnings. At least once each year they shall send to the participants or stockholders and to the supervisory body a complete balance sheet and earnings statement in the prescribed form. In this way the owners will be kept informed of the conditions of the business in such detail that there may be no criticism of irregularity or infrequency of statements or methods of presentation.

6. The federal supervisory body shall cooperate with the Bureau of Internal Revenue and the trade associations in developing for each industry standardized forms of balance sheet and income statement, depending upon the character of the business, for the purpose of reconciling methods of reporting assets and income with the basis of values and income calculated for federal tax purposes.

7. All of the companies of the character described herein may immediately adopt the provisions of this plan but shall be required to do so within three years unless the time is extended by the federal supervisory body. Similar companies formed after the plan becomes effective may come in at once, but shall be required to come in before the expiration of three years from the date of their organization unless the time is extended by the federal supervisory body.

Protection for Employees

8. For the protection of employees, the following plans shall be adopted by all of these companies:

8A. *A Workmen's Compensation Act*, which is part of the legislation necessary under this plan, after careful study, shall be modeled after the best features of the laws which have been enacted by the several states.

8B. *Life and Disability Insurance.* All employees of companies included in this plan may, after two years of service with such companies, and shall, before the expiration of five years of service, be covered by life and disability insurance.

I. The form of policy shall be determined by the association of which the company is a member and approved by the federal supervisory body. The policy will belong to the employee and may be retained by him and kept in full force when he changes his employment or otherwise discontinues particular service as outlined later.

II. The face value of a policy shall be for an amount approximately equal to one year's pay, but not more than $5,000, with the exception that the employee may, if he desires, increase at his own cost the amount of insurance carried, subject to the approval of the board of administrators, later defined.

III. The cost of this life and disability insurance shall be paid one-half by the employee and one-half by the company for which he works, with the following exception: The company's cost shall be determined on the basis of premiums at actual age of employees less than 35 years old and on the basis of 35 years of age for all employees 35 or over and shall be a face value of approximately one-half a year's pay but limited to a maximum premium for $2,500 of insurance. An employee taking out insurance at age 35 or over will pay the excess premium over the amount based upon age 35. This will remove the necessity for restriction against engaging employees or transferring them from one company to another because of advanced age, as it will place no undue burden of high premiums upon the company.

IV. The life and disability insurance may be carried by a life insurance company selected by the trade association and approved by the federal supervisory body, or may be carried by a company organized by the trade association and approved by the federal supervisory body, or a single company may be formed to serve all associations.

V. The administration of the insurance plan for each company shall be under the direction of a board of administrators consisting of representatives, one-half appointed by the management and one-half elected by the employee members. The powers and duties of the board for each company will be to formulate general rules relating to eligibility of employees, etc., but such rules shall be in consonance with the general plan laid down by the general board of administration of the trade association of which the company is a member, and approved by the federal supervisory body.

VI. Provision for the continuation of a policy after an employee leaves one company and goes to another in the same association or goes to a company in another trade association, continuance of the policy after retirement on pension, provisions with regard to beneficiaries, total or partial disability, method of payment of premiums by payroll deductions or otherwise, weekly, monthly or annually, shall be embodied in the plan formulated by the trade association, with the approval of the federal supervisory body.

VII. If an employee leaves a company to go with one which is not a member of the trade association, if he engages in business for himself, or if he withdraws from industrial or commercial occupation, he may elect to retain the portion of the policy for which he has paid in whole or in part, by the continued payment of the proportional full premium costs; or he may receive a paid up policy, or be paid the cash surrender value for the part for which he has been paying premiums. The cash surrender value of that portion of the policy paid for by the company will be paid to the company which paid the premiums.

8C. *Pensions.* All employees of companies included in this plan shall be covered by old age pension plans which will be adopted by the trade associations and approved by the federal supervisory body. The principal provisions will be as follows:

I. All employees may, after two years of service with a company coming within the scope of this plan, and shall, before the expiration of five years of service, be covered by the old age pension plan.

II. All employees after two years' service may, and after five years' service shall be required to, put aside a minimum of 1 per cent of earnings, but not more than $50 per year, for the pension fund. The employee may if he desires put aside a larger amount subject to the approval of the board of administrators.

III. The company shall be required to put aside an amount equal to the minimum stated above; namely 1 per cent of earnings of employees but not more than $50 per year per employee.

IV. The above minimum percentage shall be the same for all employees who are less than 35 years of age when payments begin and the minimum percentage for these employees shall remain the same thereafter. The percentage to be set aside by employees coming into the pension plan at 35 years of age or over shall be so determined that it will provide a retiring allowance at age 70 the same as though they had begun 1 per cent payments at age 35. These provisions enable employees to go from one company to another in the same association or to different associations at any age, with provision for retiring allowance which will be not less than the minimum rate of an employee who entered the pension plan at age 35.

V. The amounts set aside by the employee and the company with interest compounded semiannually at five per cent until retirement at age 70, for a typical average employee, would provide an annuity of approximately one-half pay.

VI. The administration of the pension plan for each company shall be under the direction of a board of administrators, consisting of representatives, one-half appointed by the management and one-half elected by the employee members. The powers and duties of the board for each company will be to formulate general rules relating to eligibility of employees, conditions of retirement, etc., but such rules shall be in consonance with the general plan laid down by the general board of administration of the trade association of which the company is a member, and approved by the federal supervisory body.

VII. The amounts collected from the employees and the companies shall be placed with a pension trust organized by the association, the management of which shall be under the direction of the general board of administration referred to hereafter. In no case shall such funds be left under the control of an individual company.

VIII. The pension trust shall invest all funds and place them to the credit of the individual employees, including the income earned by the trust. If an employee goes from one company to another in the same association, the funds accumulated to his credit shall be continued to his credit with proper record of transfer. If an employee goes to a company in another association, the funds accumulated to his credit shall be transferred to his credit in the pension trust of the associaton to which he goes. If an employee goes to a company which does not come under these provisions or which is not a member of a trade association, goes into business for himself, or withdraws from an industrial or commercial occupation, the amount of his payments plus the interest at the average rate earned by the funds shall be given to him. If an employee dies before reaching retirement age, his beneficiary will receive the amount of his payments plus interest at the average rate earned by the funds. When an employee reaches retirement age the entire amount accumulated to his credit, including his own payments and those of the company plus accumulated interest will be given to him in the form of an annuity.

If an employee goes to a company which does not come under these provisions or which is not a member of a trade association, goes into business for himself, or withdraws from industrial or commercial occupation, he may elect to let the amount to his credit (namely, his own payments plus those of the company and the accumulated interest) remain with the pension trust for transfer, if he should return to the employ of any company coming within the provisions of this plan. If he does not return to the employ of a company coming under these provisions he may at any time thereafter withdraw the amount of his own payments plus interest at the average rate earned by the funds up to that time. Company contributions and accumulated interest, credited to employees who die or for reasons indicated above receive or withdraw their own contributions and interest, shall be returned to the employer or employers who made the contributions.

IX. The rules governing the payments of pensions on retirement and all other rules governing its continuance shall be made by the trade association, approved by the federal supervisory body, and observed by the general board of administration and the boards of administration of the member companies.

8D. *Unemployment Insurance.* All employees on piece work, hourly work, daily, weekly, or monthly work, with normal pay of $5,000 per year or less (approximately $96.15 per week) shall be covered by unemployment insurance.

I. All such employees may, after two years of service with a company coming within the provisions of this plan, and shall, after five years of service, be each required to put aside a minimum of one per cent of earnings, but not more than $50 per year for an unemployment insurance fund.

II. The company shall be required to put aside an amount equal to that put aside by the employees, as set forth above; namely 1 per cent of the earnings of each employee but not more than $50 per year for each such employee.

III. If a company regularizes and guarantees employment for at least 50 per cent of the normal wage paid each year to such employees, the company assessment for employees covered by such guarantee need not be made, but the employees will pay a minimum of 1 per cent of earnings, but not more than $50 per year, into a special fund for their own benefit.

If such an employee leaves the company, dies, or retires on pension, the amount to his credit in the special fund plus interest at the average rate earned by the special fund, shall be given to him or to his beneficiaries or added to his pension.

IV. If a company so plans its work that it is able to reduce unemployment, when the amount of such company's credit in the normal unemployment fund is equal to, but not less than, 5 per cent of the normal annual earnings of the employees covered, the company may cease making payment to the fund. Employees' payments will continue. The company will resume payments when its credit in the normal unemployment fund falls below 5 per cent of normal annual earnings of the employees covered.

V. When the weekly payments made from the fund for unemployment benefits amount to 2 per cent or more of the average weekly earnings of participating employees, the company shall retire an unemployment emergency, and normal payments by the employees and the company shall cease. Thereafter *all* employees of the company (including the highest officers) receiving 50 per cent or more of their average full-time earnings shall pay 1 per cent of their current earnings to the unemployment fund. A similar amount shall be paid into the fund by the company. The unemployment emergency shall continue until normal conditions are restored, which shall be determined by the board of administrators of each company. Thereupon normal payments will be resumed.

VI. The main provisions for the distribution of the funds shall follow along these lines unless modified by the board of administrators as set forth in section D paragraph VII hereof. A certain small percentage of the normal payments of the employees and the company may be considered as available for helping participating employees in need. A larger percentage of such normal payments may be considered as available for loans to participating employees in amounts not exceeding $200 each, with or without interest, as may be determined by the board. The balance of the funds shall be available for unemployment payments.

Unemployment payments shall begin after the first two weeks of unemployment and shall amount to approximately 50 per cent of the participating employee's average weekly or monthly earnings for full time, but in no case more than $20 per week. Such payments to individual employees shall continue for no longer than ten weeks in any twelve consecutive months unless extended by the board. When a participating employee is working part time because of lack of work and receiving less than 50 per cent of his average weekly or monthly earnings for full time, he shall be eligible for payments to be made from the fund, amounting to the difference between the amount he is receiving as wages from the company and the maximum to which he may be entitled as outlined above.

VII. The custody and investment of funds and administration of the unemployment insurance plan for each company shall be under the direction of a board of administrators, consisting of representatives, one-half appointed by the management and one-half elected by the employee members. The powers and duties of the board shall be to formulate general rules relating to eligibility of employees, the waiting period before benefits are paid, amounts of benefits and how long they shall continue in any year, whether loans shall be made in time of unemployment or need, whether a portion of the funds shall be placed at the disposal of the board for relief from need arising from causes other than unemployment, tc.; but such rules shall be in consonance with the general plan laid down by the general board of administration of the trade association of which the company is a member, and approved by the federal supervisory body.

VIII. If an employee leaves the company and goes to work for another company coming within the provisions of this plan, the proportionate amount remaining of his normal contributions plus interest at the average rate earned by the funds shall be transferred to such company and to his credit. If he leaves for other reasons, dies, or retires on pension, the proportionate amount remaining of his normal payment plus interest at the average rate earned by the funds shall be given to him or to his beneficiary, or added to his pension. When such employee's credit is transferred to another company or paid to the employee or to his beneficiary under this provision, an equal amount shall be paid to the cooperating company.

9. *General Administration.* Each trade association will form a general board of administration which shall consist of nine members, three to be elected or appointed by the association, three to be elected by the employees of the member companies, and three representing the public to be appointed by the federal supervisory body. The members of the general board, except employee representatives, shall serve without compensation. The employee representatives shall be paid their regular rates of pay for time devoted to board work, and all members shall be paid traveling expenses, all of which shall be borne by the trade association. The powers and duties of this general board shall be to interpret the life and disability insurance, pension, and unemployment insurance plans, adopted by the trade association and approved by the federal supervisory body, supervise the individual company boards of administration, form and direct a pension trust for the custody, investment, and disbursements of the pension funds, and in general supervise and direct all activities connected with life and disability insurance, pension, and unemployment insurance plans.

CONCLUSIONS

The foregoing plan tends to put all domestic corporations of the class described on a parity for domestic business, thereby removing the inequalities of the different laws in the several states, provides for standard forms of financial reports and their periodical issuance for the information of stockholders, places on organized industry the obligation of coordinating production and consumption, and of a higher degree of stabilization. This will tend to assure more uniform and continuous employment for the worker and to remove fear from his mind, allowing him to devote himself whole-heartedly to his task. Cost of the product will include these items and will therefore be paid for by the users of the article or service and not in general by members of the community reached by the vicarious method of the imposition of a tax. Then organized industry will be in the position that it should rightly assume of serving the public, with public confidence and with the joint participation of workmen and management in the solution of these vital and far-reaching problems.

The following provision is suggested to place domestic corporations of the sort described on a parity with foreign competition: Any company engaged in export business may, upon application to, and approval by, the federal supervisory body, deduct from its federal income tax the equivalent of X per cent of its export sales, this X per cent deemed to be the equivalent in selling price of the various provisions for the benefit of employees which the company must make under this plan, and from which some foreign companies which the domestic companies have to meet in competition are free.

By this method American industry can discharge its obligation to its employees and by holding its position in world markets, bring additional work to America.

Synchronous Motors for Special Loads

The field of the synchronous motor can be considerably widened by variations in the design of normal motors of this type. Special requirements in starting current and in starting, pull-in, and pull-out torque can be met without resorting to unusual forms of motor design.

SYNCHRONOUS motors have been applied in recent years to drives for which only the induction motor was formerly considered suitable. This practise has resulted from the need for motors operating at unity or leading power factor and for motors having high efficiency at low speeds. The use of synchronous motors for these applications has been made possible by great improvements in starting characteristics and mechanical design as well as new methods of control.

The conventional type of synchronous motor is of course the salient-pole machine, as it permits that the field-copper space be a maximum, thus taking full advantage of separate excitation with the large number of field ampere-turns required. Due to its greater excitation capacity, the salient-pole synchronous motor may employ a relatively large air-gap, which is mechanically desirable, without impairment of electrical characteristics. Small air-gaps on the order of 0.25 per cent of the pole pitch must be used on induction motors to reduce the magnetizing kva. Mechanical limitations prevent the use of air-gaps smaller than about 0.1 per cent of the diameter, so that induction motors with more than eight poles are definitely handicapped. The normal design of the salient-pole synchronous motor permits a natural air-gap of the order of 1½ to 2 per cent of the pole pitch and mechanical limitations are not reached until the motor has 60 poles or more. For this reason, the lower the speed the more favorable are the synchronous motor char-

---

From "Synchronous Motors—Design and Application to Meet Special Requirements," (No. 31-52) presented at the winter convention of the A. I. E. E., New York, January 26-30, 1931.

acteristics in comparison with those of the induction motor.

The large air-gap also makes possible the use of larger stator slots with consequent improvement of space factor and efficiency. As high-frequency flux pulsations cannot cross a large air-gap, thicker laminations may be used in the pole pieces. Space is provided in the normal design of the pole face for an amortisseur winding with ample heat capacity to enable the motor to start most industrial loads.

The normal type of synchronous motor which is best suited for steady-load operation has the above design characteristics. However, starting and accelerating characteristics vary with speed and horsepower, and the type of load may require motor characteristics different from those given by normal design. Without abandoning the basic form of synchronous motor outlined above, the electrical design may be proportioned to attain the characteristics required for many exacting operations.

A 100-hp. 60-pole motor will have high reactance, and consequently low starting and pull-in torque, while the 1,000-hp. 20-pole motor will have low reactance and high starting and pull-in torque. The empirical curves of Fig. 1 approximate the relationship between torques at synchronous and subsynchronous speeds for 60 cycles, 450 r. p. m., and lower. It is evident that for many applications involving low-speed motors it is necessary to find means of increasing the starting and accelerating torque; while for high-speed motors it is frequently desirable to reduce both the torque and the starting inrush. For the normal low-speed machine the starting inrush is 250 to 350 per cent of the kva. rating at approximately 30 per cent power-factor lagging; while for high-speed machines the inrush varies from 500 to 800 per cent of normal rating at 30 to 50 per cent power factor.

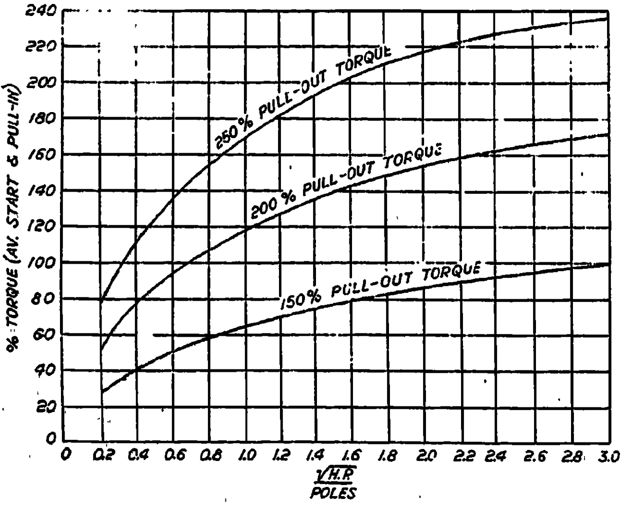

Fig. 1. Relation of starting torque to pull-out torque for various sizes and speeds of 60-cycle, unity-power-factor synchronous motors below 450 r. p. m.

REDUCTION OF STARTING CURRENT AND TORQUE

Heretofore where reduction of starting current or torque has been required, auto-transformers have been most widely used, while series reactors and resistors are sometimes used because of simplicity.

Increasing the reactance in the primary windings of the motor at starting reduces the inrush and torque without modifying the synchronous characteristics and without an external voltage-reducing device. This may be secured by the use of a double-circuit stator winding, the external connections being shown in Fig. 2. One branch of each phase is energized at start, the other branch being connected in parallel as substantially full speed is attained.

The reactance of the motor at start with only half the coils energized is much greater than with all the coils energized. The reduced current input creates less flux to act on the rotor and consequently less torque is developed, as shown in Fig. 3. As with reactor starting, the torque characteristics approach normal during acceleration. This is particularly desirable for blower and centrifugal-pump drives.

A somewhat different application of the double-winding motor is to start without shock high-torque loads such as ball mills, tube mills, and pulverizers. When the first circuit is energized, the motor develops sufficient torque to take up all gear and coupling slack. Energizing the second circuit starts and accelerates the load without shock to the mechanical parts, and voltage disturbances on the line are minimized.

INCREASE OF STARTING TORQUES

The need for starting and pull-in torques greater than those of a normal motor occurs most frequently with low-speed motors. Considering this group, the following methods are available for increasing the subsynchronous torques.

Oversize Motors. Increased torque in starting may be secured by an oversize motor, similar to the normal motor but built to larger dimensions for a given rating to make room for a greater total magnetic flux. Without restricting the magnetic section, the wide pole pieces accommodate more bars. These may be arranged on a double squirrel-cage, using high- and low-reactance elements to improve the torque per ampere and to fit the speed-torque characteristics to the load requirement. The speed-torque curves in Fig. 4 indicate the uniform torque obtainable from start to synchronism.

This type of motor is widely used on rubber mills, ball and tube mills, crushers, and on certain types of compressors. High efficiency, ample thermal capacity in the amortisseur winding, and simplicity in design, construction and control are the factors favoring this type of motor. Double-winding increment starting is available to meet objections to the sudden applications of high torque and to excessive voltage dips.

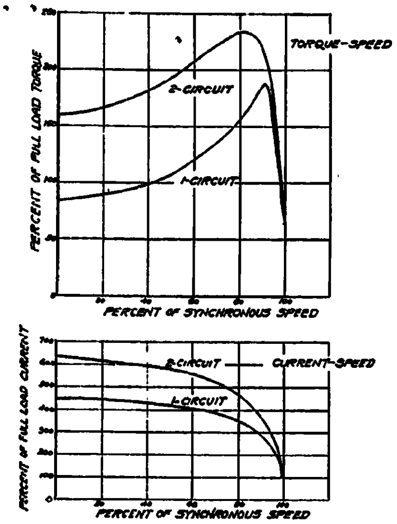

Fig. 3. Starting characteristics of an 800-hp., unity-power-factor, 1,200-r. p. m. synchronous motor with double-circuit stator winding

The use of the high-torque motor is extended by installing reliable intermittent rated capacitors for supplying part of the magnetizing current during starting. Frequently, one capacitor can be used for starting several motors, and by cutting out the capacitor in steps as the motor accelerates, the kva. demand may be regulated so as to prevent objectionable voltage variations.

Overvoltage Starting. Where high-torque design is at a disadvantage in very slow-speed rating because of excessive size, weight, or torque, a normal motor with overvoltage starting may well be applied. Overvoltage starting of normal low-speed motors does not present any difficulties to the manufacturer. With 150 to 175 per cent starting voltage, a low-speed, low-torque motor is not subjected to any higher percentage of current or torque than is a high-speed motor started on full voltage. The short, stiff end turns of the stator coils in a low-speed motor require little or no bracing to withstand starting stresses.

Overvoltage starting may be accomplished by stepping up the line voltage through an auto-transformer or by applying line voltage to only a part of a transformer primary winding. Starting torque varies as the square of the applied voltage plus a slight increase which comes from the fact that saturation decreases the starting reactance. If high pull-in torque is also required, as for starting a pulverizer with full charge, the motor can be synchronized before the voltage is reduced to normal. This is best done without interrupting power so as not to let the motor drop out of step.

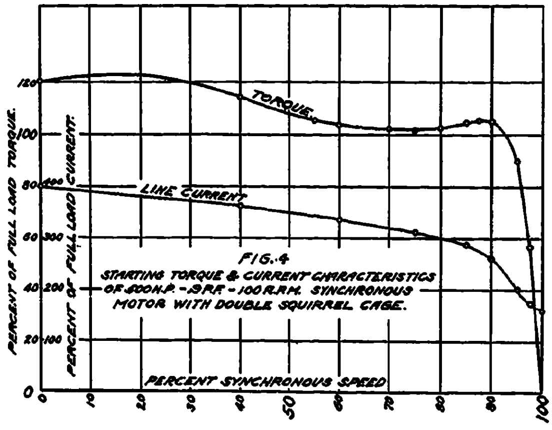

Fig. 4. Starting characteristics of a large low-speed rubber mill motor

Delta-Star Starting. Delta-star starting has been successfully used on motors required to start a heavy load with moderate inertia characteristic, but since the circuit must be interrupted in changing to normal connections after synchronizing, it is doubtful if large high-voltage circuit breakers are sufficiently fast to keep the motor in step. Moreover, no adjustment of starting characteristics is possible except in the motor design.

Tapped-Winding Starting. Where it is found that a relatively small increase in starting or pull-in torque is required, a few coils of each phase may be cut out to decrease reactance and increase input. This procedure lowers synchronous reactance, raises densities and core loss, and calls for more excitation.

In a deliberate design it is possible to arrange the end connections so that a number of coils in each phase are cut out while starting on full voltage and picked up again after acceleration, so that full synchronous reactance is restored. Tests indicate an effect similar to, but weaker than, overvoltage starting.

Phase-Wound Starting Windings. As the wound-rotor induction motor with external rheostats in the secondary circuit has excellent starting torque and current characteristics, many attempts have been made to combine these with the advantages of synchronous operation. By using such a motor with slightly larger air-gaps and fewer and larger rotor slots than normal for an induction machine, the synchronous induction motor, widely used abroad, is obtained. The slip-rings are connected to rheostats in starting, and to a d-c. source at speed. This permits a much higher ratio of starting torque to starting inrush than is obtainable in the normal motor.

The three fundamental difficulties with this type of motor are high cost, low efficiency, and high ratio of starting to rotor excitation voltage. The rotor starting voltage at full-load torque may be some fifty times the excitation voltage unless changes in connections are made. These difficulties tend to limit the application of the synchronous induction motor to a few cases of high-speed motors, where the disadvantage of increased excitation loss is minimized.

Another scheme that presents interesting possibilities is the use of a normal salient-pole synchronous motor with a phase winding in the pole phases. This scheme has the distinct advantage of permitting normal efficiency to be attained, but it introduces a more complicated mechanical construction, and does not permit as great a torque efficiency as the normal wound-rotor induction-motor construction. The phase winding must be carefully insulated and mechanically braced for high-speed motors, and this hampers accessibility of the field windings. To secure good starting characteristics and adequate heat capacity in the phase winding, it is desirable to use special pole construction at added expense. To permit full flux and torque to exist at starting, the field winding must be open-circuited, with resulting very high induced voltage unless special low-voltage excitation is used. To avoid the latter, it is customary to sectionalize the field winding while starting.

Supersynchronous Motors. The supersynchronous motor differs from the normal machine in that the external primary element is supported by bearings and is surrounded by a brake band. In starting, the primary is brought up to speed in the reverse direction and synchronized while the rotor with its connected load stands still. Gradual application of the brake slows down the primary, and starts and accelerates the rotor and load. Thus the pull-out torque of the motor is available during starting and accelerating, and rated power factor prevails. The advantages of smooth control of acceleration and controllable low starting current combined with high torque make this motor widely used in cement mills, on line shafts, mine fans, and similar applications. The design is not applicable to high-speed motors, and unless its unique characteristics are important for a specific application, it is generally preferable to use a normal-type motor with the proper control features.

One factor that should not be lost sight of is that in any group of commercial designs in standard frames, some ratings will have more favorable starting-torque characteristics than others; and in specific cases it is often possible to enlarge the amortisseur bars and increase the accelerating capacity well beyond the usual value. By this means normal-type motors may be built with an amortisseur winding to accelerate heavy loads, and much of the heat generated in the bars during a gradual acceleration passes directly into the pole pieces. The permissible temperature of the bars is not limited by contact with any insulating material. In low-speed motors the thermal capacity of the amortisseur seldom requires any modification of the normal design, because of the relatively large diameter required for a low-speed motor.

At the other extreme, two-pole synchronous motors are found to have excellent accelerating capacity in spite of the small motor diameter. By making the amortisseur in the form of very deep bars placed at the sides of rotor slots, a larger surface is provided for transferring heat to the rotor iron.

In general, for synchronizing with a large inertia, a normal motor with either a phase winding or a squirrel-cage can be designed with very low resistance to develop high torque at very low slip. It seems to be characteristic of most flywheel loads that the load at starting is not high; hence the moderate starting torque obtained with a low-resistance squirrel cage of normal reactance is usually adequate for starting loads of this type.

SYNCHRONOUS CHARACTERISTICS

The use of synchronous motors on steady loads does not present any unusual problems involving the synchronous characteristics. But where irregular loads and high momentary peaks occur, it is necessary to modify the normal design to insure successful operation.

In any application which involves wide swings of load, the first question in selecting a motor is the power supply. If the capacity is relatively large, and power swings corresponding in magnitude to the load swings are not objectionable, the first point is established in favor of the synchronous motor. If the supply is limited, and the load swings occur at very short intervals, the wound-rotor induction motor with a flywheel and a slip regulator is still in demand.

If it is found that the load swings can be assimilated by the power system, the characteristics of the synchronous motor itself must be considered. For any practical case involving peak loads of the order of one-half second duration or more, three alternatives are possible in applying a synchronous motor:

1. Provide a motor with sufficiently high sustained pull-out torque to carry the load without losing synchronism.
2. Remove excitation and allow the motor to run on the amortisseur winding, resynchronizing after load has been reduced.
3. Automatically apply excess excitation to motor field during heavy overloads.

The first method, which amounts to building an oversize motor, is particularly applicable where the load swings occur frequently. Although unity power-factor motors can be designed to develop 300 per cent pull-out torque or more by resorting to a very large air-gap and low-armature reaction, such motors in general will be larger than leading power-factor motors which develop the same pull-out torque. Since the synchronous motor is often chosen primarily for power-factor improvement, motors of 80 per cent or even 70 per cent leading power factor are commonly selected.

Even with this torque available, motors are occasionally thrown out of step by extreme overloads, and a study must frequently be made of the flywheel effect of the machine, together with the sustaining torque of the amortisseur winding, to determine whether the motor can carry through the peak load without too great a reduction in speed. With adequate data the speed reduction can be estimated closely; and if this is not too large, the duty of accelerating back to synchronous speed will not endanger the amortisseur winding, since the heating of this element for a given output, varies with the slip.

After a motor has been forced out of synchronism, the d-c. excitation must be removed temporarily since otherwise the motor would generate a braking torque in opposition to the accelerating torque of the amortisseur winding. Then the load must be limited also to a value which will enable the motor to resynchronize, the means of limiting this load depending upon the type of load.

For meeting such conditions where the motor may be pulled out of step frequently, the synchronous induction motor would be well suited except for the inherently low pull-out torque of this type. If designed for good starting characteristics, unity-power-factor designs will have only 120 to 140 per cent pull-out torque. By designing for 0.8 leading power factor, 175 to 200 per cent pull-out torque can be obtained. If the overexcitation is further increased to obtain still higher synchronous torque, the loss in efficiency may be serious. Obviously, the wound-rotor machine can be justified only by very severe accelerating duty or starting current requirements.

Many possibilities for increasing pull-out torque are presented by quick-response excitation. If a synchronous motor is subjected to occasional peak loads much greater than the average load, and the field excitation can be quickly increased to meet these overloads, a material reduction in the size and cost of the motor is sometimes possible. In addition, the motor may be designed for best efficiency at the average load condition, and the motor power factor will be held more nearly constant during the load changes. The problem is the same as that involved in overexcitation of generators to maintain synchronism during short circuits, except that most industrial motor installations cannot justify the refinement and expense of the equipment used with large generators.

When a heavy load is suddenly applied, a synchronous motor can momentarily exert a torque far greater than its sustained maximum torque. This usually gives sufficient current for changes in excitation to be made, provided the excitation system is sufficiently fast. In the larger motor sizes, modification of the exciter may be necessary to increase its rate of voltage rise. For small motors, such as 100-hp., usually it will be more economical to build a motor having this higher torque inherently, than to resort to overexcitation with a larger exciter and additional control.

Another method of overexcitation which is sometimes used is to operate a 125-volt exciter at 175 or 200 volts for example, and dissipate the difference between this value and 125 volts in a fixed resistor in series with the motor field. A contactor is then used to short-circuit the resistor when the motor load exceeds a predetermined value.

Interesting possibilities are found in the use of electron tubes for overexciting a synchronous motor, although this has not yet been applied commercially. In applying any field-forcing scheme, the motor field must be of liberal design so that the intermittent high excitation will not overheat the field coils. With adequate margin provided, however, the field winding can still be considerably smaller than that of an equivalent high-torque motor which carries high excitation current continuously.

Severe Lightning Tests Made on "Surge-Proof" Transformers

AN INTERESTING SERIES of lightning tests was made on Sunday, August 23, by the Westinghouse Electric and Manufacturing Company on each of four 42,000-kva., 220-kv. single-phase transformers. These units are of the new non-oscillating surge-proof type of construction recently developed by this company, which states that the transformers embody features of insulation design effecting greatly improved impulse strength.

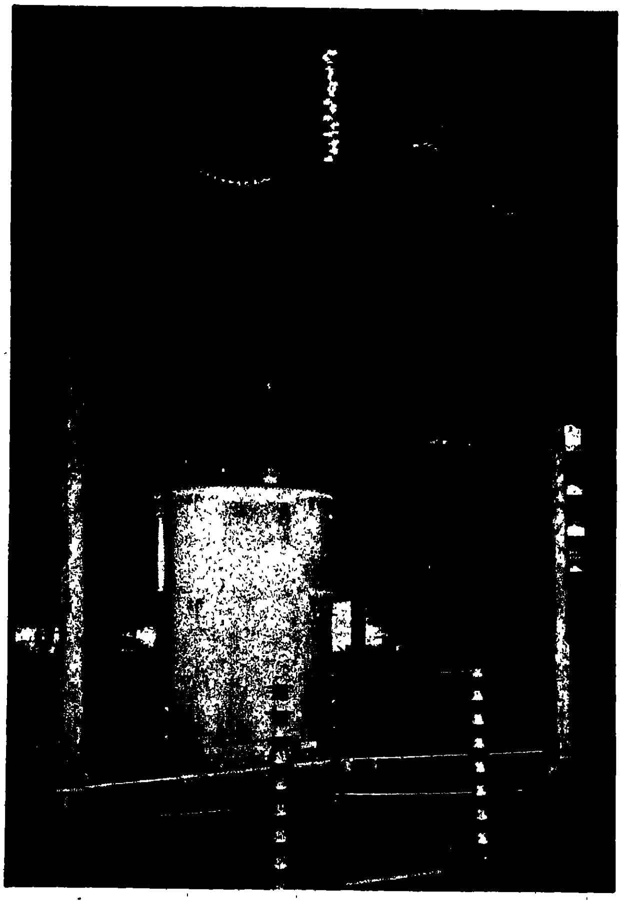
These tests are claimed to be significant for two reasons: first, that the transformers are by far the largest commercial transformers on which actual lightning tests have been made; and second, that the tests were much more severe than any heretofore applied to a commercial transformer. Each transformer was set up with a 64-in. protective gap, and connected to the surge generator with a short line supported by a string of fourteen standard insulator disks. The following tests then were carried out:

1. Several long-wave surges were applied to the transformer, the voltage being raised gradually until flashover of the protective gap took place.
2. The gap was then removed and long-wave surges of still higher voltage applied until the string of fourteen standard insulator disks flashed over.
3. The insulator string was replaced by one having twenty-one disks and the voltage increased until flashover of the transformer bushing occurred.

4. In order to simulate a direct stroke of lightning, a surge which rose to the flashover value of the protective gap was applied in a small fraction of a microsecond.

The first three of these tests proved that the requirements of coordination between the four elements, transformer insulation, bushing, line insulation, and protective gap, had been met. They also showed that the longest waves that could reach the transformer, even with an over-insulated line and no protective gap, produced no internal oscillations to overstress the insulation between the winding and ground.

The steepest wave front produced by natural lightning which has been recorded to date was found by Pittman and Torok (see ELECTRICAL ENGINEERING for July 1931, p. 494) to have a rate of rise of 4,000 kv. per microsecond. The wave front used in the fourth test above was nearly three times as steep as that measured by Pittman and Torok. It was thus proved that the transformer would withstand surges representative of the severe conditions of a direct lightning stroke on the line close to the apparatus. At no time during these tests did the transformer show any signs of distress. After the lightning tests were completed, the regular A. I. E. E. insulation tests were repeated as further evidence that the transformer had suffered no damage.



Flashover of line insulator with fourteen standard disks at approximately 1,300,000 volts

Relaying with Two Pilot Wires

The fastest relay scheme for isolating a faulty section of transmission line is the pilot-wire system. This usually requires four wires between stations, and therefore cost limits its application to short sections of line. A modified scheme is described herewith which reduces the number of wires needed.

By
C. H. FRIER
Oklahoma Gas & Electric Co., Oklahoma City

PILOT-WIRE RELAYING for transmission lines has the advantage of giving fast operation and of being independent of the setting of selective relays. With the usual definite time relays, the time settings of the relays must be increased in each successive section of line. This means that the section near the generating station frequently has such long settings that low-voltage conditions during faults on the system may exist long enough to drop synchronous equipment out of step. In certain cases, other forms of relays may be applied to obviate this difficulty, but the pilot-wire scheme is ideal from the standpoint of quickly isolating the faulty section of the line. It is especially advantageous in eliminating the difficulty of relaying on complex loops and networks.

The usual scheme of pilot-wire relaying consists of balancing the secondary currents of current transformers at both ends of the line. This requires four pilot wires between stations, and their cost usually limits the application of this scheme to short lines. The telegraphic pilot-wire relay scheme developed by the Oklahoma Gas and Electric Company requires one, or preferably two, pilot wires, and is therefore applicable to relatively long lines. It insures quick isolation on the occurrence of any type of line or ground fault where there is a source of power at both ends of the transmission line section. In addition to the pilot-wire relays the usual selective relays are used as back-up protection against the failure of the pilot wire. A supervisory system can be installed and is desirable to enable the operator to check the conditions of the telegraphic circuit at any time. Also, this circuit may be used simultaneously for telephone communication.

From "Telegraphic Pilot-Wire Relay System" (No. 31M13) to be presented at the A. I. E. E. South West District meeting, Kansas City, Mo., Oct. 22-24, 1931.

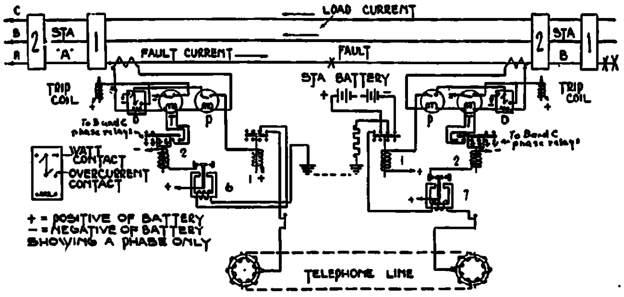


Fig. 1. Fundamental scheme of pilot-wire relay system

To remove hazards to life or equipment all current and potential transformers are grounded securely.

It usually will be more desirable for the operating company to lease the pilot wires from the telephone company than to own and maintain its own lines, as telephone wires strung on the high-voltage line towers are not feasible due to the high induced voltages; separate structures therefore are necessary.

The pilot-wire scheme consists essentially of directional and non-directional overcurrent relays at each end of the line, operating on low current flow into the section being protected. Current flow from either station into the line causes these relays to operate a transfer relay at the same station. The contacts of these transfer relays at both ends of the line are in series with each other through the pilot wire and ground return. The occurrence of a fault on the line section causes the current relays at both ends to operate, energizing both transfer relays, the contacts of which close the telegraph-wire circuit. Thus through auxiliary relays the tripping coils of the oil circuit breakers on both ends of the line are energized.

The details of the fundamental scheme are shown in Fig. 1, the current relays in phases *B* and *C* being identical to those shown for phase *A*. The watt contacts of the directional overcurrent *D* close when current is flowing away from the station bus. The overcurrent contacts of relays *D* are given relatively high current and time settings and form the secondary or "back-up" system. Relays *T* and *P* are overcurrent relays of the pilot-wire scheme and are given low settings. Upon the occurrence of a short circuit at *X*, the watt contacts on relays *D* and the overcurrent contacts on relays *P* at both stations *A* and *B* operate. This energizes transfer relay 1 at each station which closes the pilot-wire circuit through the operating coils of relays 6 and 7. These latter in turn energize relays 2 which remove the short circuits from the current coils of relays *T*. These are given instantaneous time settings, and current settings only slightly over the maximum load current so that when a fault occurs on the section and the short circuit is removed from the operating coils of relays *T*, both circuit breakers are tripped at the same time. Although only one pilot wire with ground return may be used, the use of two pilot wires and ground return as shown in Fig. 1 gives more reliable operation. These lines are usually leased in pairs, and by connecting them through a repeating coil at each end, satisfactory operation may be secured even with an open circuit on one line or a short circuit between lines, provided there are no grounds.

The purpose of the overcurrent phase selective relays *P* is to isolate the watt contacts of relays *D*. If the latter were connected in parallel, incorrect operation would result during certain cases. For example, if these watt contacts in each phase were not isolated and a short circuit occurred at *X X*, circuit breaker 1 at station *A* and circuit breaker 2 at station *B* would be opened. Considering the relays of circuit breaker 1 at station *A*, relay *P* and the watt contact of *D* in phase *A* would, of course, close due to fault current and energize the transfer relay at station *A*. Considering the relays for circuit breaker 2 at station *B*, load current would tend to close the watt contacts of relay *D* in phases *B* and *C*, and the contacts of relay *P* in phase *A* also would be closed by the fault current. It is apparent therefore that if these watt contacts were not isolated by relays *P* in each phase, the transfer relay would also be energized to complete the circuit through the pilot wire and trip the circuit breakers on the good section of line.

A lock-out scheme, the elements of which are shown in Fig. 2, further insures correct operation. The operating coil of multi-contact relay 8 is connected in parallel with that of transfer relay 1 of the switch on the opposite side of the same station. Relay 8 short-circuits the current coil of relay *P*. A fault at *X* which would cause circuit breaker 2 at station *A* to open would also energize lock-out relay 8 of circuit breaker 1 at station *A*, so that this latter circuit breaker could not open on through fault. This is desirable as the opening of circuit breaker 2 might set up transients which would close the watt contacts of the relays on circuit breaker 1. This condition would result if a synchronous condenser, a generator, or a transformer bank with the high-voltage side connected star and having its neutral grounded, were connected to the bus at station *A*.

A supervisory system, shown in Fig. 3, is used to give a continuous indication of the condition of the pilot

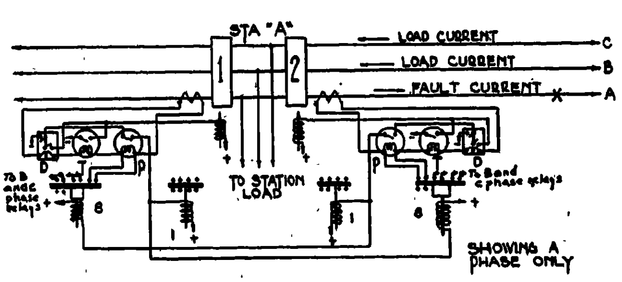

Fig. 2. Lock-out scheme of pilot-wire relay system

and wire to indicate operation of the equipment. Any operations of either the supervisory relay 4 or of the polarized relay 2 will give an indication on the recording voltmeter. The supervisory relay circuit is energized at all times unless the pilot-wire circuit fails or an operation of the transfer relay 1 occurs. Normally, the contacts of relay 4 are in the closed position and due to the resistor in the circuit the voltmeter reads slightly lower than battery voltage. If relay 4 is de-energized due to an open circuit or a ground in the pilot wire, the voltmeter will read zero and an alarm will sound. At station *B*, relay 3 will remain energized on a grounded pilot wire, but an increased reading on the milliammeter will result.

The telephone system by which the operators at two stations may communicate with each other is also indicated in Fig. 3. When it is desired to test the condition of the pilot-wire system the operators communicate with each other by telephone, and then operate the push-buttons in each station to cause both transfer relays to become energized. If there is no trouble on the pilot-wire system the alarm will sound.

Provision is made also for instantaneous clearing of a faulty section in the event of a substation operator closing a circuit breaker on a faulty line after the circuit breaker has tripped. This is accomplished by connecting the coil of relay 9 in parallel with the circuit breaker closing coil. Relay 9 is energized by pulling the closing button and then closes its contacts to remove the short circuit from the tripping relays *T*. If the current is abnormal, the switch will trip immediately without the assistance of the pilot-wire features.

One of the refinements which may be utilized is the use of a single pilot-wire installation protecting two parallel transmission lines. This scheme requires additional polarized relays which function only when current is flowing in one direction.

There are 193.5 mi. of actual telegraphic lines used by the Oklahoma Gas & Electric Company for the protection of its 66-kv. system. Over a period of five months, and during the most inclement weather, the total outages of the pilot wires amounted to 182.5 hr. or 36.5 hr. per month. During the first six months of 1931 there were 38 correct operations and only three incorrect operations. These were all caused by lightning closing the telegraph relays at one station while there was trouble on the adjacent section. Cycle counter tests have revealed that the entire equipment functioned in from 9 to 12 cycles, and with unvarying precision.

Although the telegraphic pilot-wire system is applicable to loops and networks only or where current is flowing into a fault from both directions, its use has been found to be justified by its quickness of operation on all types of line and ground faults. Since it is frequently necessary to lease wires from the telephone company for communication purposes, and the same wires can be used for the pilot-wire relay system, the additional expense in such cases is small. Another advantage is that where a power system is expanding rapidly, this pilot-wire relay scheme can be applied without rearranging the entire relay system.

Experiments With Short Arcs

Observations were made on all phases of the arc discharge, including the transition period between the glow and arc stages. Current density at the cathode is shown to be the factor determining when that transition will take place, rather than the temperature of that element as was thought formerly.

By
G. M. SCHRUM University of British Columbia, Vancouver

H. G. WIEST, JR. General Electric Co. West Lynn, Mass.

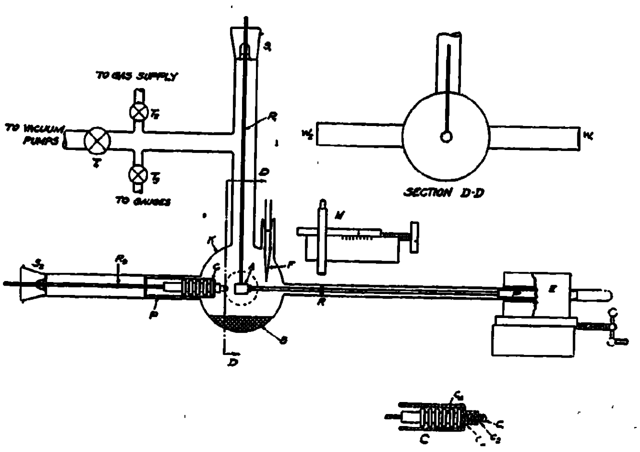

Fig. 1. Apparatus for studying the characteristics of low-current arcs in different gases

PHENOMENA associated with arc discharge between cold metallic electrodes are unusually complex, and in general not well understood. In view of the growing use of the arc commercially, especially in industrial welding operations, a further study of the physical mechanism underlying this particular type of discharge seems warranted. This investigation is concerned chiefly with short arcs (a few millimeters) between iron and copper electrodes in air and some of the inert gases, the gas pressures ranging from atmospheric to about 1 mm. of Hg. Particular attention has been devoted to the transition period between the so-called abnormal glow discharge and the actual striking of the arc.

Previous investigations have shown that this transition period is quite abrupt and many workers have doubted even the existence of such a transitory region. One common belief is that as the glow spreads over the electrode surface, the cathode gradually becomes heated sufficiently at some point to start an arc. In the present tests, however, a continuous transition was observed not only from the glow to the arc, but also in the reverse direction. The results indicate also that current density at the cathode rather than the temperature of that electrode is the factor determining when the transition takes place.

In the first series of tests a number of experiments were made on the arc discharge itself with currents ranging from 1 to 20 amperes. The arc current was supplied from a 250/500-volt d-c. generator, the current being adjusted by means of an external series resistance. In order to obtain reproducible results electrodes of approximately the same size and shape were used throughout, a convenient size having been found to be 1/8—3/16 in. in diameter and 2 in. long.

CHARACTERISTICS OF ARCS IN VARIOUS GASES

In this group of tests, results in general were found to agree fairly well with those of previous investigators. Steady arcs could be maintained in all cases in air or carbon dioxide, while in hydrogen, argon, and nitrogen, the arcs were either unsteady or would not strike at all. At lower pressures the arcs were less stable for all gases.

During some of the experiments, electrodes which had been used for arcs in air were found to give steady arcs later when used in argon. Further investigation showed that this phenomenon was due to oxidation of the electrodes when used in air, the same degree of arc stability being obtained in argon with electrodes oxidized by other methods. In addition it was found necessary to treat the cathode only; a stable arc could be maintained with a clean iron anode, and an oxidized cathode in argon and nitrogen, and also for a short time in hydrogen. With the electrodes reversed, that is, using a clean cathode and an oxidized anode, the arcs were unstable in these gases.

Further observation showed that when an arc was struck in various gases with the treated cathode, the cathode spot was established at the point where the electrodes had been in contact, and remained stationary; with the clean electrode this spot wandered so rapidly over the surface of the cathode that the arc soon broke. In order to investigate this characteristic further, a flat plate cathode was made, part of the surface of which was oxidized, the remainder being clean. When an arc was struck on the oxidized surface, it remained steady, but when struck on the clean surface it wandered as before but did not cross over on to the

2-mm. arc between copper electrodes in commercial argon under 2-cm. (Hg.) pressure

oxidized portion. On the basis of these tests the oxide seems definitely to prevent wandering of the cathode spot since other tests showed that this characteristic was not due to the roughness of the oxidized surface. This point is of particular note when it is considered that if the spot is prevented from wandering, the cathode temperature rises locally at that spot, and a steady arc results.

Tests in Dry and Moist Gases

In addition to the foregoing experiments, tests were made for the purpose of comparing arc characteristics in both dry and moist air and argon, respectively. Results of the tests in argon showed that the voltage drop across the arc in moist or argon was from 15 to 20 per cent greater than for the dry gas. Also the arc was found to be much more stable in moist than in dry argon especially at low currents, due perhaps to the oxidation which took place in the moist gas. Similar results were obtained for the tests in moist and dry air respectively, although the difference in arc drop was not quite so great.

The principal significance of the results of these particular tests is that if water vapor can be supplied to an arc used in welding the general effect would be to raise the potential drop of the arc, and thus for the same current increase the rate of melting.

To supplement the information already obtained, spectroscopic observations were made to determine which electrode contributed the greater amount of vapor to the arc stream. For this purpose a Hilger constant deviation glass spectrograph was used. Relatively low currents were employed for these experiments so that little or no fusion of the cathode took place. Results showed that the spectra in each case was typical of the cathode material although a few faint lines due to vapor from the anode were observed. The degree of excitation at the cathode thus is indicated to be much more intense than at the anode.

Transition Between Glow and Arc Discharges

In this portion of the study apparatus was arranged so as to enable the discharge characteristics to be observed between current values of 1 microampere and 2 amperes. A diagram of equipment used may be seen in Fig. 1, while Fig. 2 shows schematically the electrical connections. The arc chamber *K* consists of an 8-in. Pyrex bulb, electrodes being supported by the molybedenum rods R_1 and R_2 sealed in ground glass stoppers S_1 and S_2. To limit the area of cathode exposed to the discharge so that the region of the abnormal cathode glow might be explored properly, the cathode was made with two quartz protecting tubes C_2 and C_3, and with a large ribbed copper sleeve C_4 for cooling purposes. With this arrangement the cathode area exposed was about 0.22 sq. cm. The length of the arc gap was determined by a traveling microscope *M* with suitable scale, in conjunction with knife edge *R* attached to the rod of the soft iron plunger *P*. Glass beads *B* in the bottom of the bulb served to prevent drops of molten metal from cracking the glass. The heavy tungsten filament *F* serves to clear the bulb of all traces of oxygen in the argon.

For currents of from 1 to 100,000 microamperes switches S_1 and S_2 (Fig. 2) were closed. When the current values were such that the kenotron *U* was required, switch S_3 was in position 1; during those portions of the test in which the desired current variations could be obtained by external resistance S_3 was thrown to position 2. For currents from 0.05 to 5.00 amperes a UV-214 type kenotron was used, while for the lower currents a smaller three-element tube with grid and plate tied together was employed.

Arc-voltage readings were taken with various types of electrodes for currents varying from 1 microampere to 2 amperes. For this portion of the investigation observations were made on the galvanometer *G*.

Within this range of current it was possible to trace the development of the discharge from the corona or brush discharge through the normal glow and into the region of abnormal glow. A typical curve obtained from data taken in this manner for copper electrodes separated a distance of 2 mm. in commercial argon at 2-cm. (Hg.) pressure is shown in Fig. 3. Examination of this curve will reveal the fact that the volt-ampere characteristic is negative for the brush and normal glow discharges, becoming positive for the abnormal glow discharge. While the maximum voltage reached in the abnormal glow period varied somewhat an average value was of the order of 500 volts, and the corresponding current about 100 milliamperes. As the current was increased still further, the arc voltage decreased steadily until a drop of from 30 to 50 volts was reached, at which time the discharge exhibited all the characteristics of the true arc.

Due to the excessive heating of the cathode and of the protecting refractory material, difficulty was experienced in obtaining reproducible results within the transition region between abnormal glow and arc discharges. To overcome this difficulty, a large kenotron (UV-214 type) was employed for limiting the arc current, and an oscillograph was used to study the rapid changes occurring within this region, the two elements being connected as shown at E_1 and E_2 (Fig. 2).

To obtain the desired observations, the temperature of the kenotron filament was adjusted so as to give an arc current of about 2 amperes. The arc was then struck and switch S_4 (kenotron filament switch) was opened. As the filament temperature dropped, the arc current gradually decreased, the discharge passing through the various low-current stages. Oscillogram records were obtained simultaneously with this operation. Transition from the abnormal glow to the arc discharges was observed by starting with the normal glow discharge, then closing S_4, the kenotron filament switch; this gradually increased the arc current thereby causing the discharge to pass through the abnormal glow and into the arc stage, simultaneous oscillograph records being obtained as before.

A typical oscillogram showing the changes occurring between arc and abnormal glow is shown in Fig. 4 which was made with a short arc between copper electrodes in argon at a pressure of 25 cm. (Hg.). The duration of this experiment is indicated by the 60-cycle timing wave. In Fig. 5 is shown the volt-ampere characteristic plotted from the data given in Fig. 4. The transition from arc to glow was found to be quite abrupt. In other tests the transition from glow to arc was found to be practically identical and to take place at practically the same voltage and current values as the change from arc to glow. Since the time required for the kenotron filament to reach any particular value of discharge current must be different in the two cases, the transition would appear to be governed more by the cathode current density than by its temperature.

At lower pressures the transition between arc and glow was observed to be more gradual. This was true especially with short arcs. Thus it is quite obvious that both high pressures and long gap lengths tend to produce sudden transitions.

Results of these experiments indicate clearly the presence of a definite transition phase between the abnormal glow and arc discharges, although the volt-ampere characteristic for this stage is quite abrupt. Also current density at the cathode is shown to be the principal factor determining when this transition takes place rather than the temperature of that electrode. This contention is supported by other experiments in which the exposed area of the cathode was increased. In these, much higher currents were required before the arc could be developed, in spite of the fact that the electrode temperature occasionally was high enough to cause fusion.

An extension of this study of the transition from glow to arc and from arc to glow under various conditions appears to be a line of investigation which should lead to interesting results. An arrangement permitting the control and accurate measurement of electrode temperature especially that of the cathode, together with oscillograph records of the transition stages, should lead to a better understanding of the actual mechanism by which electrons are emitted from the cathode.

Repulsion Starting for Capacitor Motors

The characteristics of single-phase motors are improved considerably by the addition of a capacitor winding on the stator. High torque and low current during starting also can be secured by the use of a repulsion type of rotor.

By
EDWARD BRETCH
Member A. I. E. E.

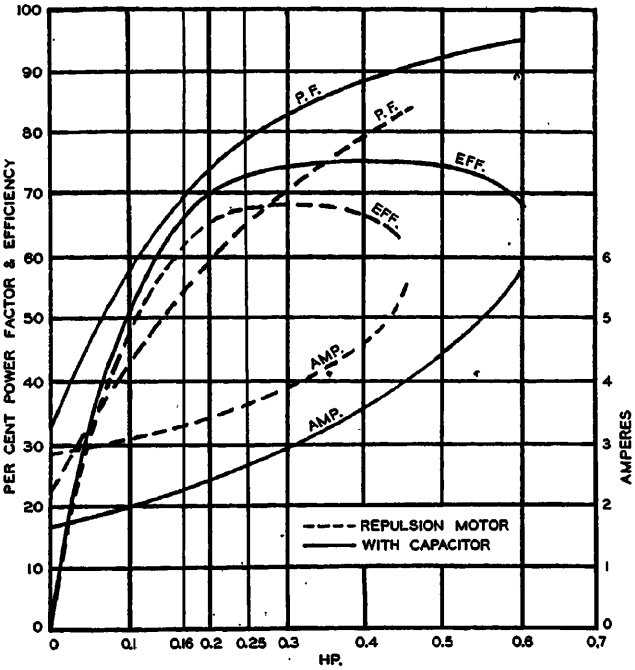
Advance Electric Co.
St. Louis, Mo.

THE DEMAND for single-phase motors with better electrical characteristics, together with the development of reliable and inexpensive capacitors, has encouraged the use of the capacitor motor. The stator of this motor has a second single-phase winding connected in series with a condenser and energized from the supply line. With this form of single-phase motor it is possible to approximate the efficiency and quietness of a polyphase motor, and at the same time to improve greatly the over-all power factor.

The problem of starting capacitor motors is about the same as in the case of single-phase induction motors without capacitor winding. Two general methods are available; the split-phase or rotary-field method of starting with a squirrel-cage rotor, and the commutator or repulsion method, in which the rotor currents are commutated for starting, and are short-circuited at running speed to operate as a squirrel-cage motor.

In the capacitor motors so far developed, split-phase starting and a squirrel-cage rotor have been used. With this means it is possible to use the capacitor winding as the split-phase winding during starting. Where a fixed condenser and a squirrel-cage rotor provide efficient starting torque, and the starting currents are not objectionable, this split-phase method of starting is desirable. However, where the locked rotor and low-speed torque must be exceedingly high, and heavy starting currents are objectionable, the repulsion method of starting has a considerable advantage over the split-phase method. Accordingly, an investigation was made of the practicability of a repulsion-starting capacitor motor; that is, a motor starting by the repulsion method but having a capacitor phase-winding on the stator.

The stator of a 1/6-hp. standard repulsion-induction motor was rewound for capacitor operation; the repulsion rotor was used for starting and then when up to speed was short-circuited in exactly the same manner as with the standard repulsion-induction motor. As shown by the curves, this capacitor winding had the effect of increasing the efficiency, power factor and output of the motor. Due to the increased efficiency, the capacitor motor operated at the same temperature rise at ¼ hp. that it did as a 1/6-hp. plain repulsion-induction motor, corresponding to about a 50 per cent increase in output. Also, it tended to eliminate noise, combining the better running characteristics of the capacitor motor with the starting characteristics of the repulsion-induction motor. Repulsion starting provides the same starting characteristics for the capacitor motor that it does for the plain induction motor, giving high locked-rotor torque with low locked-rotor current.



Characteristics of 1/6-hp. standard repulsion motor, and as rewound for a 1/4-hp. repulsion capacitor motor

Comparing a ¼-hp. repulsion-capacitor motor with a split-phase capacitor motor of the same rating, it was found that although the pull-out torque of the repulsion motor was less than that of the split-phase motor, and the full-load torques were the same, the locked-rotor torque of the repulsion motor was considerably greater. Also, the locked-rotor current and energy of the repulsion motor were reduced by more than half, and the full-load efficiency and power factor were increased.

Another advantage of the repulsion-capacitor motor is that a 7.5-μ f. condenser could be used in series with the capacitor winding for both starting and running, while the split-phase capacitor motor required a 7.5-μ f. condenser for running, and a 45-μ f. condenser for starting. In the event of condenser failure the repul-

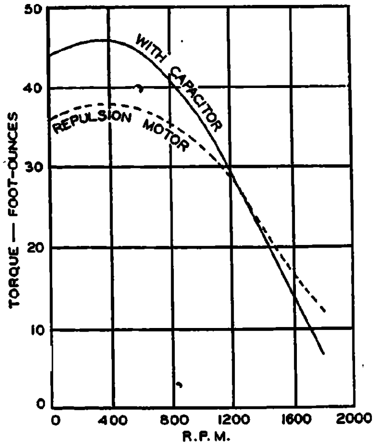
Written especially for Electrical Engineering. *Not published in pamphlet form.*



Speed-torque curve of standard repulsion motor, and with a condenser connected permanently in the capacitor phase

sion-starting capacitor motor can still be operated as a plain repulsion-induction motor. Further, the equipment is fundamentally more substantial and reliable, as no overvoltage or surge is imposed upon the condenser at starting.

Considering both squirrel-cage and repulsion motors, together with their condensers and accessories, there is some question as to which will be the more costly. In the repulsion-capacitor motor, the extra cost of the capacitor winding is not so great as in the squirrel-cage capacitor motor, as in the former the condenser is of small size and can be connected permanently in the circuit, eliminating any automatic cut-out or the switches required for starting with the split-phase method. Although the addition of a capacitor winding increases the cost of a motor, the fact that a smaller motor may be used for a given output will in part, at least, overcome this extra cost.

On applications where the starting conditions on single-phase motors are severe, the repulsion-capacitor motor has a decided advantage over the other types and should be practicable on all sizes of motors, from the smallest to the largest.

Distribution Systems for Industrial Plants

THE PLANNING of an electric distribution system for industrial plants may be divided into two distinct parts: (1) determination of the electrical characteristics, and (2) the physical arrangement of the system. Under these two headings W. J. McClain (associated with Louis T. Klauder, consulting engineer, Philadelphia, Pa.) discusses the problem in a very general way in a current A. I. E. E. paper.

In designing the physical layout of the system, the author points out that the plot plan of the plant, together with present and future building plans, should be studied carefully. The manufacturing processes and equipment set up in the plant also should be studied, and a digest of system requirements compiled in order to arrive at a satisfactory solution for any particular plant. Single-line diagrams with arrangement sketches should be drawn for comparative solutions, ranging from maximum economy of design to maximum reliability or continuity of service. These diagrams may be amplified to include such features as voltage regulation, power-factor correction, and various types of switching equipment.

In conclusion the author states that a comparative tabulation of different solutions should be compiled showing relative costs, losses, space requirements, special building construction, efficiency of operation, continuity of service, and maintenance. This comparative tabulation reduces the various solutions to a basis from which a final solution may be selected, or a compromise effected to include desirable features of any of the solutions considered.

Electron Tubes for Industrial Control

ELECTRON TUBES have been in every-day use in radio and other communication fields for many years. It is only recently, however, that the field of application has been extended to include industrial usages, and while the gross number of industrial installations employing electron tubes is not enormous, important progress has been made in applying these new electrical tools to the problems of industry.

In a current A. I. E. E. paper, W. R. King of the General Electric Company, Schenectady, N. Y., outlines the fundamentals of operation and the practical aspects of the application of some of the more important of these new and interesting devices. Included in his discussion are the photoelectric tube, the three-element grid-controlled rectifier tube, and the grid-controlled mercury vapor rectifier.

From "Electrical Distribution Systems for Industrial Plants" (No. 31-29) presented at the A. I. E. E. winter convention, New York, N. Y., Jan. 26-30, 1931.

From "Electron Tubes in Industry" (No. 31-30) presented at the A. I. E. E. winter convention, New York, N. Y., January 26-30, 1931.

"Vacation Convention" a Noteworthy Success

VIEWED from every angle the twentieth annual Pacific Coast convention held at Lake Tahoe, Calif., August 25-28, was notably successful. The official registration was 247, not a record so far as Pacific Coast attendance goes, but notwithstanding exceeding many a similar gathering held in "better times." All technical sessions were called to order on scheduled time and were exceptionally well attended; discussions were widely participated in. Golf, boating, water sports, mountain climbing, trout fishing, and trips to nearby points of historic or scenic attraction were participated in according to personal preference.

Fully half of those present were "on their own time," taking in the convention as a part of a family vacation trip. This feature is significant in several ways and well may serve as a guide-post to those planning future conventions.

The technical program comprised four sessions accommodating 17 papers prepared by 25 men. Such of these as were not previously published in ELECTRICAL ENGINEERING in comprehensive form were abstracted in ELECTRICAL ENGINEERING, September 1931, pp. 753-6, and hence will not be treated here. Some of these papers were of strictly local interest, while others were of wider general interest; all were well received. Several of the papers provoked extensive discussion, both extemporaneous and written. On pp. 835-7 of this issue may be found a comprehensive abstract of the salient points covered by such of these discussions as were submitted to Institute headquarters within the prescribed time limit.

Two sessions devoted to their papers and a student breakfast conference drew many Enrolled Students to the convention. Papers presented at these sessions included:

SHORT-CIRCUIT CALCULATION, C. L. Holmes, State College of Washington.

LABORATORY STUDY OF TRANSMISSION LINES, D. J. Moore, A. A. Petrick and D. D. Johnson, University of Washington.

RESIDUAL CURRENTS AND VOLTAGES IN POWER SYSTEMS, C. A. Bairos and G. S. Kimball, Stanford University.

EFFECTS OF SHORT CIRCUITS UPON THE STABILITY OF A TRANSMISSION SYSTEM, S. G. Winkler, University of Southern California.

INFLUENCE OF PRESERVATIVES ON THE DIELECTRIC STRENGTH OF WOOD, C. B. Parsons and M. H. Tipton, Oregon State College.

SOME ELECTRICAL METHODS OF GEOPHYSICAL PROSPECTING, F. M. Holly, Jr., Montana State College.

VACUUM-TUBE VOLTAGE REGULATORS, E. W. Palmrose, University of California.

THYRATRON INVERTER, G. A. Ross and L. W. Russell, California Institute of Technology.

THE REFLEX THERMIONIC VOLTMETER, L. W. Thorpe, University of Santa Clara.

ACOUSTICS OF KINGSBURY HALL, F. Lundberg and F. N. Neal, University of Utah.

TORQUE ANGLE CHARACTERISTICS OF SYNCHRONOUS MOTORS, W. F. Arndt, California Institute of Technology.

SOUND PICTURE SYSTEMS, Charles Douglas, University of Nevada.

C. E. Grunsky of San Francisco, Calif., president of the American Engineering Council, presented the feature address of the convention at a general session held the evening of August 26. Men and women alike paid close attention to this dissertation on "Business Cycles and Some Economic Problems" in which the speaker's penetrating insight and rare personality enabled him to present in a most interesting and illuminating fashion some of the fundamental causes underlying the recurring cycles of business activity. The speaker reviewed the situation rather comprehensively saying relatively little directly concerning the current economic disturbance, but pointing out the striking similarity existing between the current depression and those which have occurred periodically during the past century.

Having established the fact that history repeats itself so strikingly approximately every 20 years, Mr. Grunsky mentioned several important contributing factors including human shortsightedness and taxation inequalities, stressing the unfairness of our present political tax bonus system. He discussed also the rigid and destructive inflexibility of the dollar (or any other unit of money) as a measure of value where the element of time enters into a given transaction, presenting statistics revealing the varying purchasing power of the dollar (or any other money unit) during the past century. He suggested and strongly urged that with the present system of money as an exchange medium, and with a "commodity unit" to serve as a basis of evaluation supplementing the money unit, many evils now commonly encountered would be obviated. With the use of the commodity unit or "com" as a basis of valuation, the sale of services or commodities involving a period of time would be made on an agreed basis of so many "coms," thus assuring for buyer and seller an equitable deal. Payment of course, would be made in dollars or any other normal money unit according to the relation existing at the time of payment between the "com" and the money unit.

Of course, the principal sporting event was the annual golf tournament for the John B. Fisken perpetual trophy. Some 60 entrants enjoyed keen competition in three classes for the large group of valuable prizes. Honors for the day went to M. S. Barnes (M'31) of the San Francisco Section who by virtue of his low net score of 61 (78-17) captured the Fisken Trophy and a set of six matched irons. Others who shared in the prizes were G. R. Murphy (F'20), W. G. B. Euler (A'08), W. L. Winter (A'21) and Nathan Cohn (A'29) of the San Francisco Section; and C. C. Boozier (A'23) of the Portland Section. Kickers' prizes went to G. M. Rosenblatt (M'17) San Francisco Section; David Hall (F'18) Los Angeles Section; and C. C. Boozier (A'23) Portland Section. Honors in the women's putting contest went respectively to Mrs. A. V. Thompson and Mrs. A. G. Jones, San Francisco; Mrs. L. C. Williams, Los Angeles; and Mrs. D. M. Peterson, San Francisco.

The reception for President Skinner and the convention banquet constituted the two formal social affairs. A tremendously successful barbecue dinner held on the Tahoe Tavern tennis courts, and enlivened by the Neapolitan Trio of radio fame, introduced a series of informal social affairs very apparently enjoyed by all. The final event was "A Night in Monterey," a Spanish cabaret put on by the Tavern management.

Other entertainment features included a women's bridge tea, a three-hour steamboat trip down Lake Tahoe to scenic Emerald Bay, a presentation of Will Rogers's "Connecticut Yankee," and a playlet "What's the Use?" presented by local talent under the direction of A. C. Joy, San Francisco, depicting humorously the overthrow of a trained and established engineer by a correspondence-school graduate who had a diploma certifying to his mastery of engineering via a 90-day course.

President Skinner Traces Trend of Electrical Engineering

The convention was formally opened by General Chairman A. W. Copley promptly at 9:30 a. m. August 25, with a full attendance. Mr. Copley introduced Dr. C. E. Skinner, president of the Institute, whose opening address sketched, decade by decade, the trend of thought in electrical engineering as represented by the published record in the A. I. E. E. TRANSACTIONS. Excerpts from Doctor Skinner's address follow:

"The Institute's first meeting was held in Philadelphia in October 1884, and the first paper found in Vol. 1 of the TRANSACTIONS is by Dr. Edwin J. Houston on 'Phenomenon' now known as the Edison effect. . . It seems to me quite fitting that the first paper published should refer to work of Thomas A. Edison, the pioneer in incandescent electric lighting as well as in so many other fields.

"Curiously enough in this same volume is found a paper on a system for placing wires under ground and providing subways for electric traction under the streets of New York; another with the curious title 'The Earth as a Circuit Completer.' Attention is given to multiplex telegraphy and to electroplating; and very considerable discussion is recorded of the inadequacy of the patent office to deal properly with electrical inventions. I have heard this same discussion in recent years. In this discussion it is stated that prior to 1880 there were fewer than 2,000 patents recorded in the United States Patent Office having anything whatever to do with electricity.

1884–1890

"Subsequent volumes of the TRANSACTIONS between 1884 and 1890 contain some extremely interesting papers on various subjects. . . For example, in Vol. 4, 1887, appears a paper. . . 'Distribution of Electricity by Secondary Generators' outlining schemes with which my own more than 40-year career has been intimately associated. This paper was the announcement before the Institute of the a-c. system espoused by George Westinghouse and outlining the Gallard-Gibbs scheme of what we now know as the a-c. system of distribution by the means of transformers. . . Another paper which excited my interest, and some amusement, was a long paper, followed by a very extended discussion, on 'A New Arc Lamp Clutch.' It is also noteworthy that the men of prominence of that time referred to themselves and each other as 'electricians' and not as electrical engineers, and one wonders how it came about that the original name of our organization was chosen as the American Institute of Electrical Engineers. While I have not read carefully, I do not recall seeing the term 'electrical engineer' used in any of the volumes prior to 1890.

"The period from 1884 to 1890 was of course the real pioneer period of both the Institute and the electrical industry. It was a period of cut-and-try methods. The term 'industrial research' had not been coined, but even so, relatively great advances of this period can be assigned to relatively few experimenters, most of whose names appear in the Transaction of the Institute, and in many cases as past-presidents of the Institute. It was during this early period that the first limited electric light plants were installed and operated, and the electrification of street railways begun. . . A paper read in 1886 states: 'The central station of today is a very large and cumbrous arrangement. There are many engines in rapid motion and exposed to many dangers and interruptions. There is an air of gloom and anxiety on every face. The unseen tremendous power, not always under control, which is consumed at uncertain times and at invisible points, may be made to react at any moment with destructive energy.'

1890–1900

"The period between 1890 and 1900 was one of exceedingly rapid development and betterment in the design of electrical machinery, the means of measuring electric current, and the rapid extension of central stations and isolated electrical plants in buildings and factories. The TRANSACTIONS of the Institute reflect these advances and contain the fundamentals of the history of the electrical developments of the period. . .

"It was during this period that the great project of Niagara Falls came to fruition with the transmission of great amounts of power to more than twenty miles, and this was really the beginning of electric power as a commodity. The Tesla polyphase a-c. motor had been announced prior to 1890, but it was only during this decade that the polyphase motor became a commercial product. In the early nineties means of measuring alternating current were very unsatisfactory; the best instruments of precision we had for this purpose when I entered the Westinghouse laboratories were the Cardew hot-wire voltmeter and the Siemens electrodynamometer for current. However, much more satisfactory instruments appeared before the end of the decade. It was during this period also that the first high-voltage transmission plants were constructed in the West, the first of these being the so-called Pomona (Calif.) transmission at 11 kv.; and it is interesting to note that due to our lack of experience in the building of high-voltage transformers we used twenty 110/550-volt transformers with secondaries in series and primaries in parallel. The modern street-car motor in all of its essential principles appeared. . . in the summer of 1890. . .

1900–1910

"The next decade, from 1900 to 1910, was characterized by extremely rapid extension of electrical plants throughout the world, and the development of larger and more efficient electrical machinery. . . more efficient prime movers, particularly the steam turbine. . . It was the heyday of the street railway, and it was during this period that many important inventions. . . appeared. One of these which has had a profound influence was the development of silicon steel. Prior to the middle of this decade, electric steel was merely a refinement of the steel used for other purposes, and the losses particularly in transformers were giving a great deal of trouble. . . By the end of 1906 silicon steel, invented by Sir Robert Hadfield of England, was in general use both in this country and abroad, and the intrinsic loss had been cut in half and aging entirely eliminated. Many refinements and improvements have been effected since that time and much of the history of the magnetic art may be found in our TRANSACTIONS. Through the reduction of losses in electrical apparatus by the use of this steel hundreds of thousands of tons of fuel have been saved.

"One of the subjects which might be dealt with in a paragraph in any of the decades from 1900 to the present time is that of lightning protection. While I have not checked pages it is my belief that there are perhaps as many, possibly more, pages in our TRANSACTIONS devoted to lightning phenomena and lightning protection than any other single specific subject. . . It may be asserted, however, that. . . even in the beginning of the present decade, 1930 to 1940, the complete and final solution of lightning protection is yet to be effected.

1910–1920

"The period from 1910 to 1920 was a period of the further expansion of electrical plants, the further increase in the output and efficiency of electrical machinery, and the real beginning of the use of electricity in household devices and in industrial heating. The automobile had begun to take toll from interurban traction, and to a certain extent from city traction lines. In the previous decade electrification of the steam railways in congested areas had reached considerable proportions, and the old a-c.-d-c. battle was fought over again in connection with heavy electric traction. . . The mercury-vapor converter had entered as a factor, particularly in Europe, and at the same time the rotary converter had been brought to a very high degree of efficiency and perfection. . .

1920–1930

"The decade from 1920 to 1930 certainly may be characterized as the period of consolidation and interconnection. . . It may be of interest to note here that after a study of transmission made during my senior year in college (1889-1880) my class definitely proved that electrical transmission of light and power never would be profitable to a distance of more than five miles. We now transmit power by the a-c. system, then almost unknown, in very large quantities many hundreds of miles, and sooner or later we no doubt will be interconnected in our plants from the Atlantic to the Pacific. . .

". . . We are just as much interested, (and perhaps more so) in the future as we are in the past. Both the manufacturers and the utilities now have research departments intensively engaged in attempting to peer into the future, and in devising new applications, new materials, and new equipment. They are carrying on much fundamental research, many times with no immediate hope of commercial returns. . . It would be a bold prophet who would predict that radically larger units, more efficient prime movers, or better transmission systems would not be forthcoming; but for the present we seem to be more or less at a standstill in this line. The use of household devices is certainly on the rapid increase. . . One of the extremely interesting developments now going on is that of air-conditioning in our homes and offices, and even in our workshops and trains. . .

"I have not even mentioned some of the most sensational developments that have been made in fairly recent years, such as radio.

"We electrical engineers have been accredited, or perhaps accused of being responsible, along with other branches of engineering, for our present depression through our making it possible for the individual worker to produce much more than by older methods. It is certainly true that the machine age has brought us a host of problems that must be solved by us or by our children. As engineers we must go forward as we have in the past, bringing greater efficiency, greater comforts, more commodities, and greater production by the individual workmen. As citizens we must do our part in bringing the same sort of efficiency to our local state and national government. We must humanize our engineering. Surely some of the evils of today should yield to analysis and cure by the same general methods which have proved so effective in solving the multitude of far-reaching difficulties that have beset us as electrical engineers in the years compassed by our American Institute of Electrical Engineers.

Last Call for Kansas City Meeting

Kansas City, Missouri, host city to a three-day meeting of the South West District No. 7 of the A. I. E. E., has completed plans which will provide both a profitable and enjoyable time for those in attendance, October 22-24. Headquarters will be at the Kansas City Athletic Club.

Four technical sessions will be held during the meeting. These should prove of particular interest to the utility planning engineer as well as the utility operating engineer and all who are engaged in telephone communication work. In connection with the St. Louis-Bagnell interconnection session which will be held on Thursday evening, a three-reel motion picture of the actual construction of the Bagnell dam will be shown.

The local committee has arranged a variety of inspection trips to points of unusual interest embracing up to date electrical applications. Some of these features consist of new supersynchronous motor installations for the cement mills, the completely automatic distribution system of the Kansas City Power and Light Company, automatic installation of the Southwestern Bell Telephone Company, and the Bagnell water power project.

The chief social event of the meeting—the meeting banquet—will be held on Friday evening, Oct. 23. Entertainment will be provided by some of the best talent obtainable and following the banquet there will be dancing. Special plans have been made to care for women guests.

A detailed program of this meeting, together with a list of the papers to be presented, was published in ELECTRICAL ENGINEERING, September 1931, pp. 757-9.

District Executive Committees Meet at Tahoe

A business meeting of the combined executive committees of Districts Nos. 8 and 9 and the western portion of District No. 10 (Canada) was held at Tahoe Tavern, Lake Tahoe, Calif., August 26, 1931, as a luncheon gathering. Those present included: *president*, C. E. Skinner; *national secretary*, F. L. Hutchinson; *vice-presidents*, H. V. Carpenter and A. W. Copley; *District secretaries*, C. E. Baugh and R. D. Sloan; *Section chairmen*, E. A. Crellin (San Francisco), P. S. Biegler (Los Angeles); *other Section representatives*, W. C. Smith (San Francisco), H. W. Hitchcock (Los Angeles), O. B. Coldwell (Portland), C. B. Carpenter (Seattle), J. H. Hamilton (Utah), H. T. Plumb (Utah), F. W. MacNeill (Vancouver, B. C.), and J. A. Thaler (Montana).

The first order of business was the assignment of the 1932 Pacific Coast convention which was awarded to the Vancouver (B. C.) Section with the dates tentatively set as August 29-September 2 inclusive. The 1933 Pacific Coast convention was tentatively awarded to the Utah Section.

Student participation in future conventions was a subject which aroused thoughtful and active discussion. Based upon experience with the Lake Tahoe convention, E. A. Crellin, the new chairman of the San Francisco Section, strongly urged that for future Pacific Coast conventions the usual convention committees be augmented by the addition of a "committee on student participation." Mr. Crellin suggested that the duties of such a committee should include primarily (1) attention to the question of suitable housing for students in attendance at the convention, and (2) assisting in and coordinating the work involved in the handling of student sessions, the securing and advance circulation of student papers, and the stimulation of discussion at student sessions by the choosing of "key" men to start such discussions.

Student Activities Discussed at Lake Tahoe

At a student activities conference held in connection with the Lake Tahoe convention August 27, and presided over by G. L. Hoard, student counselor, University of Washington, Seattle, several problems pertaining directly to the conduct of these student conventions were discussed. Concurrent student sessions were considered undesirable. A motion was passed authorizing next year's committee to select student papers on a competitive basis (rather than by allotment to schools as at present) such competition to be effective only after each Branch had been given an opportunity to present one paper for consideration. Arising out of a discussion of the problem of getting student papers in in time for intelligent selection, a motion sponsored by the students themselves was put through, urging the establishment of a definite deadline date for student technical papers.

As a result of discussions pertaining to the several problems involved in publishing, or otherwise reproducing in some reasonable quantity, the officially accepted student papers, it was suggested by several that either the student Branches themselves, or the educational institutions with which they were affiliated might provide the necessary finances for this work. Other questions discussed included ways and means of getting before high school students authentic vocational guidance information pertaining to electrical engineering courses, and possible methods of enhancing student interest and student participation in Branch activities.

Out of the fourteen student Branches of the Institute in Districts Nos. 8 and 9 and the western half of District No. 10, thirteen were represented at this student activities conference. Twelve of the student chairmen were present (representing all Branches except those at the University of Nevada and the University of British Columbia) and nine of the student counselors were present. Student counselors present included: F. O. McMillan, Oregon State College, S. G. Palmer, University of Nevada, O. E. Osburn, State College of Washington, R. H. Hull, University of Idaho, W. G. Angermann, University of Southern California, J. H. Hamilton, (for A. L. & R. Taylor) University of Utah, R. W. Sorensen, California Institute of Technology, L. E. Reukema, University of California, and E. F. Peterson, University of Santa Clara (Calif.). Student chairmen present included: M. R. Jones, Jr. Stanford University, R. C. Hansen, University of Utah, D. H. Hansen, Oregon State College, P. F. Hawley, University of Arizona, A. S. Koch, University of Washington, G. E. Gage, University of Idaho, H. T. Lambdin, Montana State College, D. H. Olney, State College of Washington, P. B. Lyons, California Institute of Technology, V. T. Johnson, University of California, M. C. Marshall, University of Southern California. and L. W. Thorpe, University of Santa Clara.

Summarized Review of Some Pacific Coast Convention Discussions

ONLY discussion submitted in writing in accordance with governing A. I. E. E. rules is summarized; complete discussion together with all approved papers will be published in the TRANSACTIONS. Abstracts of all papers presented at the convention and not previously treated in ELECTRICAL ENGINEERING, were given on pages 753-6 of the September issue.

INDUSTRIAL APPLICATIONS

G. B. Rosenblatt (San Francisco, Calif.) discussed the economic side of "Electric Power in the Wood Products Industry." He explained that increasing taxes on standing timber had caused an over production in lumber which allowed but little or, in come cases, no margin of profit. Therefore, in order to realize a profit the industry will turn toward an increased number of fabricating processes and more uses of the wood waste, both of which will result in a greater consumption of kilowatt-hours.

K. M. Patterson (East Pittsburgh, Pa.) also discussed this paper with special reference to the application of synchronous motors. He pointed out that in the sizes used in the lumber and paper industries synchronous motors usually represent a savings in first cost over other types of motors, with the additional advantages of high efficiencies and controlled power factor. He also explained that the development of full magnetic control with adequate protective features had kept pace with the improvement of motor characteristics.

R. O. Brosemer (San Francisco, Calif.) and J. L. Wright (Portland, Ore.) discussed this paper and pointed out that their experience based on a number of actual surveys made in typical sawmills in the Pacific Northwest indicated that electric power consumption varied from 45 kw. to 60 kw. per 1,000 board feet. Another point brought out by them referred to the possible inference in Table II that synchronous motors should be used for all main drives in modern sawmills, and induction motors only for secondary drives. Notwithstanding the advantages and improvements in synchronous motors they felt that due to their simplicity and usually lower first cost, there was still a legitimate field in induction motors for such main drives.

David Hall (Los Angeles, Calif.) discussed "Electrical Equipment for Oil-Field Operation" referring to the progressing evolution from steam to electricity. He told of recent improvements made by his company regarding mud-pump drive. These consisted of wound-rotor induction motors with permanent resistance and reactance in the rotor circuit, an arrangement which provides a motor which will slow down under increasing loads and actually stall before the pumps can be injured. He also explained that rotary drilling using a completely electrified rig of the Hild differential type recently successfully completed the deepest well in the world, drilled to a depth of 10,030 ft. He further explained that d-c. equipment was developed to meet the demand for drilling "wild cat" wells.

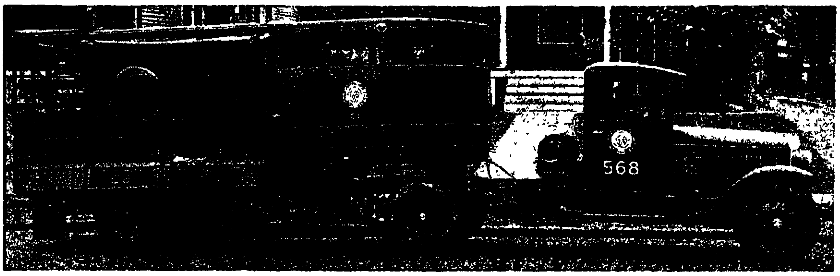
ELECTRICAL MACHINERY

P. L. Alger's (Schenectady, N. Y.) discussion of "Correlation of Induction-Motor Design Factors" was presented by J. H. Cunningham (Los Angeles, Calif.). Mr. Alger drew attention to the magnitude of the task and said that he believed it was theoretically possible and very desirable, to express all the electrical and mechanical constants of a motor, and lso its cost, as explicit functions of its principal dimensions. Thence the optimum values of all dimensions could be determined for any desired evaluations of cost and performance.

R. E. Hellmund's (East Pittsburgh, Pa.) views on this subject were presented by David Hall. He pointed out that the designer usually is forced by many practical conditions to depart from the ideal, and that the author's method had the same limitations as all other methods of analyzing and carrying through design work by a simple set of formulas. If all essential considerations are taken into account, the method becomes cumbersome or else numerous assumptions have to be made which do not properly take into account all factors of practical importance. The second fundamental assumption in the author's theory used the ratio of the flux densities in the teeth and the core. Mr. Hellmund did not believe that the choice of this factor as an important variable was particularly desirable because this ratio did not represent anything very basic in the design of the motor. It can be, and frequently is, varied over wide limits without materially affecting the final results.

G. E. Creed and R. J. Thompson (Hamilton, Ont.) in their discussion of this subject which was presented by V. B. Wilfley (Portland, Ore.) called attention to several pertinent considerations including power factor (especially on slower-speed motors), iron losses, ventilation, proportion of length of coil ends to active length, starting current, starting and pull-out torques, and the necessity for using commercial wire sizes. They pointed out that these considerations usually would require an appreciable departure from the theoretically best dimensions which give minimum stator resistance in order to obtain a good practical design.

New Type of Truck for Line Crew



ADDED to the motor fleet of the Cleveland (Ohio) Electric Illuminating Company is a new unit which has proved so satisfactory that a second is being built. The vehicle is designated as a "tractor-type semi-trailer" and is constructed so that the trailer can be detached and left at the scene of an operation, while the tractor is free to engage in such transportation work as may be required. Its fully enclosed cab provides comfortable seats for twelve men, well safeguarded against traffic accidents. There is ample space within the body for all sizes of tools, the compartments being arranged so that the tools most frequently used are on the outside. The unit is of all-metal construction, sturdy and weatherproof.

A. H. Barth's discussion of this paper was presented by R. W. Sorensen (Pasadena, Calif.). It explained that the author has been given an opportunity by an electrical manufacturer to try his method of analysis in the laying out of new designs and adding larger sizes to older lines where the dimensions of the component parts could be made any value which would give the most satisfactory motor and not be governed by the necessity of adapting a particular motor to an existing frame. The author has been very successful in this work and the paper is the result of his having filled the need for simple manner of determining optimum motor dimensions mathematically instead of by the rather empirical methods which now are in general use.

R. W. Sorensen also discussed this subject explaining that the Hoover analysis enables one in the early stages of design, to consider mathematically, and thus accurately, more of the variables which have to do with the relations between punching diameters both internal and external, core depth, and slot dimensions, thus reducing the element of guess work, and making possible a more accurate selection of the rating to which a given punching is best adapted.

E. A. Crellin and F. I. Lawson (San Francisco, Calif.) discussed "Calorimeter Measurement of Stray Load Losses on Generators." They analyzed test methods to determine stray load losses and presented data on generator losses obtained by the retardation method from efficiency tests made on a number of hydroelectric units. They cited that the information presented by the authors, giving an independent determination of stray load losses, was a distinct contribution to the hydraulic as well as to the electrical engineer.

Power Transmission and Distribution

J. W. Bennett's (Springfield, Mass.) discussion of "A-C. Networks in Portland, Oregon" was presented by G. Ross Henninger (New York). The discussion drew attention to the cost of the duplicate primary system adopted in Portland, as compared with the system having a radial primary and network secondary. The discussor cited several local conditions each of which would be variable in different localities, and stated that these of course would influence the design and development of a distribution system. He believed the difference in favor of the system adapted was due to conditions existing in Portland. Results of a recent comparative study made by J. W. Bennett were in favor of a low-voltage network system supplied at 13-kv. secondary transmission voltage for areas having a well distributed load of 5,000 kva. per sq. mi.

H. S. Fitch's (Pittsburgh, Pa.) discussion of "Tie Line Control of Interconnected Networks" was read by S. B. Clark. The discussion told of the operating problem of the Pennsylvania-Ohio-West Virginia interconnection from the early beginning up to the present time. Tie line control on this interconnection first was attacked from the point of view of frequency control.

Nathan Cohn (San Francisco, Calif.) presented Philip Sporn's (New York) discussion of this subject which reviewed the problem as related to the operation of interconnected systems. It was the experience of Mr. Sporn that automatic frequency control on each of two systems operating on parallel has been found to reduce greatly the fluctuation on a tie line, and in one instance it was the only practical means of operating the systems in parallel through a relatively weak tie line. This statement is contrary to the findings in the paper discussed.

P. B. Garrett (San Francisco, Calif.) presented a discussion prepared by John Gosinski (Jackson, Mich.) which drew attention to the operation of tie-line load regulators. It was pointed out that the purpose of an interconnecting tie line was to transfer large blocks of power in an emergency, and that any regulating device should preserve this feature of an interconnection.

Dr. W. A. Lewis (East Pittsburgh, Pa.) presented Robert Brandt's (Boston, Mass.) discussion of this paper which also brought out the necessity of frequency control as a step in the solution of the major operating problem. He believed the mechanical devices described in the paper had been well thought out and that they serve their purpose admirably. In particular, reference was made to the explanation of the anti-hunting feature which takes into account the momentum that has to be established and later destroyed in bringing the system from one load condition to another.

A discussion by Edith Clarke (Schenectady, N. Y.) on "Tuned Power Lines" was read by G. Ross Henninger. By means of vector diagrams, Miss Clarke arrived at the same results as those expressed by Professor Skilling in his paper, (that a transmission line of wavelength slightly over a half wave, including the terminal machine impedance, has good operating characteristics and that power may be exchanged between a synchronous generator at one end of such a line and a motor at its other end, while for the line slightly under half wavelength little or no synchronous power can be transmitted).

Communication

G. T. Rouden (San Francisco, Calif.) discussed "Intercontinental Radiotelephone Service from the United States," explaining that the International system had circuit in operation handling telegraph business between New York and Madrid via Buenos Aires. This avoids the difficulties experienced with an east-west circuit such as that over the North Atlantic. He also mentioned the downward trend in the cost of long-range antenna systems. The high steel tower construction used during and just following the war period now has been superseded by the simple double-V antenna supported by common wood poles only 70 ft. high. The new and less costly construction provides efficient operation over a wide range of frequencies and is expected to make feasible the extension of communication facilities to many localities which otherwise could not be reached economically.

P. G. Caldwell (Stanford Univ., Calif.) discussed "Electrical Measurement of Sound Absorption," explaining that when sound energy is "absorbed," it is converted into heat energy by a process which involves a friction between the absorbing material and the oscillating air particles. Therefore sound-absorbing material will be most effective when it is placed where the air particles are oscillating with maximum velocity. This position always is a quarter-wavelength distant from a sound radiator or hard reflecting surface. The data in Fig. 5 of the paper are not in accordance with the foregoing explanation. Possibly one reason for the apparent discrepancy lies in the fact that the radiator was a dynamic loudspeaker. There is some question as to what point on the loudspeaker cone should be considered as a reference when taking data such as that in Fig. 5.

ELECTROPHYSICS

H. H. Skilling (Stanford Univ., Calif.) discussed "The Kindling of Electric Sparkover" quoting similar conclusions from a report of a study made at the Ryan laboratory. These conclusions concerned superposed 60-cycle and impulse phenomena between points; they supported the three conclusions in the paper.

S. S. Mackeown (Pasadena, Calif.) discussed the theory of the spark discharge to show just what is difficult to understand today. He referred to the early theory of Townsend's and the work of Rogowski and others which found that the time necessary for a spark discharge to occur was of the order of 10^{-8} sec. He explained that the pictures in Doctor Magnusson's (Seattle, Wash.) paper were a record of what occurred probably of the order 10^{-5} sec. Therefore it would seem dangerous to draw conclusions regarding the actual formation of a spark from the data presented in that paper.

RADIO COORDINATION

J. J. Smith's (Schenectady, N. Y.) discussion of this subject was presented by C. F. Green (Schenectady.) He cited several points which showed that the question of responsibility is more involved than would be assumed from the three last paragraphs in the section entitled "Responsibility" in the paper. He believed the work done by the authors would be of considerable value if carried out in quantitative manner so that measurements in one locality could be compared with those in another.

J. O'R. Coleman (New York) interestingly discussed this problem and drew attention to the question of definition of interference as applied to radio. He referred to the study of the coordination of power and telephone systems, which revealed that the problem naturally divided itself into a study of power system influence, coupling between the two systems, and susceptiveness of the telephone system. He believed the same treatment could be applied in the handling of radio coordination. It was explained that a joint committee of representatives of the R.M.A., N.E.L.A., and N.E.M.A. had been formed to study the problem.

F. B. Doolittle (Los Angeles, Calif.) discussed this subject emphasizing the need for a better distribution of broadcast coverage in California. He showed a map of the state in which the areas enjoying reasonably good reception were designated and might be compared with the total area of the state. It was believed California had a sufficient allotment of broadcast power and frequencies to serve the area adequately, but that the geographical distribution of stations was not good. Reliable service is not available to large areas while inconvenience is worked upon other places by an excessive number of stations.

Nomination of 1932 Institute Officers

Actions specified in the Institute's constitution and by-laws relative to the organization of a national nominating committee are being taken, and the meeting of the national nominating committee for the nomination of officers to be voted upon at the election in the Spring of 1932 will be held between November 15 and December 15. All suggestions for the consideration of the national nominating committee must be received by the secretary of the committee at Institute headquarters, New York, not later than November 15.

The sections of the constitution and by-laws governing these matters are quoted below:

Constitution

28. There shall be constituted each year a national nominating committee consisting of one representative of each geographical district, elected by its executive committee, and other members chosen by and from the board of directors not exceeding in number the number of geographical districts; all to be selected when and as provided in the by-laws; the national secretary of the Institute shall be the secretary of the national nominating committee, without voting power.

29. The executive committee of each geographical district shall act as a nominating committee of the candidate for election as vice-president of that district, or for filling a vacancy in such office for an unexpired term, whenever a vacancy occurs.

30. The national nominating committee shall receive such suggestions and proposals as any member or group of members may desire to offer, such suggestions being sent to the secretary of the committee.

The national nominating committee shall name on or before December 15 of each year, one or more candidates for president, national treasurer and the proper number of directors and shall include in its ticket such candidates for vice-presidents as have been named by the nominating committees of the respective geographical districts, if received by the national nominating committee when and as provided in the by-laws; otherwise the national nominating committee shall nominate one or more candidates for vice-president(s) from the district(s) concerned.

By-laws

SEC. 22. During September of each year, the secretary of the national nominating committee shall notify the chairman of the executive committee of each geographical district that by November 1 of that year the executive committee of each district must select a member of that district to serve as a member of the national nominating committee and shall, by November 1, notify the secretary of the national nominating committee of the name of the member selected.

During September of each year, the secretary of the national moninating committee shall notify the chairman of the executive committee of each geographical district in which there is or will be during the year a vacancy in the office of vice-president, that by November 15 of that year a nomination for a vice-president from that district, made by the district executive committee, must be in the hands of the secretary of the national nominating committee.

Between October 1 and November 15 of each year, the board of directors shall choose five of its members to serve on the national nominating committee and shall notify the secretary of that committee of the names so selected, and shall also notify the five members selected.

The secretary of the national nominating committee shall give the fifteen members so selected not less than ten days' notice of the first meeting of the committee, which shall be held not later than December 15. At this meeting, the committee shall elect a chairman and shall proceed to make up a ticket of nominees for the offices to be filled at the next election. All suggestions to be considered by the national nominating committee must be received by the secretary of the committee by November 15. The nominations as made by the national nominating committee shall be published in the January issue of ELECTRICAL ENGINEERING, or otherwise mailed to the Institute membership during the month of January.

Signed F. L. HUTCHINSON,
National Secretary

October 1, 1931

H. L. Doherty Finances Unemployment Research.—Press reports of September 9, 1931, recorded the statement that Henry L. Doherty (A'98-F'13) widely known public utility operator has made available to the American Society of Mechanical Engineers a fund of $500,000 to provide for a study of the present industrial situation and to work out ways of remedying it.

Annual Safety Congress to be Most Extensive

The twentieth annual safety congress and exposition under the supervision of the National Safety Council is to be held in Chicago, October 12-16, 1931. An impressive list of 130 sessions with more than 300 speakers has been assembled for this conference which is to cover all the various organized fields of safety work. The public utilities section is an important part and represents about 400 organizations with more than 900,000 employees. The meetings of this section are to be held on October 13, 14, and 15. Another important group is the electric railway section which holds meetings on the same dates.

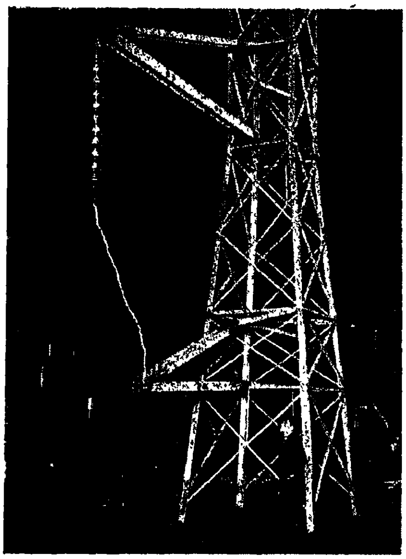
In addition to the sessions for specific industries there will be a number of special industrial sessions. Among these are sessions on industrial health and industrial psychology. One of the features of the congress will be the annual safety exposition in the large exhibition hall of the Stevens Hotel, where more than 100 exhibitors will display a panorama of standard safety equipment and the latest developments in safety appliances. This will be the most extensive and fully rounded safety congress ever held. It is significant that during these times of economy industrial safety activities have not slackened.

Executives to Visit Research Laboratories

A distinctive tour for industrial executives and bankers to important research laboratories has been arranged for October 5 to 15, 1931, under the auspices of the National Research Council. The purpose of the tour is to demonstrate the importance, value, and varied applications of research in industry, and by personal observation to study the operation and compare the different types of successful laboratories. The trip is similar to one made last year by a party of 100 selected industrial executives and bankers, and from which a number of very important by-products resulted.

The group will leave New York October 5 on a steamer for Boston; then continuing by train will visit research laboratories in the eastern part of the country. Dinners and accommodations have been arranged to insure the success of the trip. The laboratories to be visited are those of the Massachusetts Institute of Technology, Dewey and Almy Company, Arthur D. Little, Inc., Thompson and Lichtner Company, and the United Drug Company, all in Boston; the Eastman Kodak Company in Rochester; the Ford Motor Company and proving grounds at Detroit; Nela Park at Cleveland; Goodyear Tire and Rubber Company, and the Zeppelin Plant at Akron; the Basic Science Research Laboratories and Tanners Council at the University of Cincinnati, both in Cincinnati; Battelle Memorial Institute at Columbus; and the Westinghouse Electric & Manufacturing Company at East Pittsburgh. The executives of these laboratories are offering their fullest cooperation toward the success of the tour.

Indoor Tower Tests



SETTING a precedent for indoor lightning investigations, according to reports, the full-size section of 132-kv. transmission tower shown in the accompanying illustration recently was set up in the Westinghouse laboratories where 3,000,000-volt surges are available from an artificial lightning generator. The set-up was made to study the behavior of a wooden crossarm construction specified by the Union Electric Light & Power Company (St. Louis) for a new transmission line from its Osage plant to Rivermines station. During the test, Stone and Webster engineers found that it took 1,800 kv. to flashover the string of insulators when hung from the wooden crossarm, as compared to 1,100 kv. to flashover the same string with the usual steel supports. The man standing in the picture to show comparative sizes departed from the vicinity before the flash shown occurred.

Illuminating Engineers to Hold "Silver Anniversary"

Beginning October 12th, the Illuminating Engineering Society plans a four-day silver anniversary convention to be held at the William Penn Hotel, Pittsburgh, Pa. Reflecting in full measure the importance of the occasion, an outstanding technical program has been provided which has kept pace with the latest and newest developments in lighting practise and technique. A pre-convention meeting for central-station lighting service engineers will be held on October 12, and the Hon. James Francis Burke will give the address of welcome to the opening session on the morning of October 13. An architectural lighting session will be held that afternoon, and on the following day there will be a session on aviation lighting and an evening meeting which will include the conferring of honorary membership upon Dr. Elihu Thompson (Charter Member F'13-HM'28, and past-president) and Prof. André E. Blondel (A'05-HM'12). Lighting service and lighting practise sessions will be held on the following two days. Novel entertainment will feature the annual banquet and dance in the main ballroom of the William Penn Hotel on Thursday evening. Ideal golfing facilities will be available at the St. Clair Country Club. Special consideration is being given to women guests by a Committee appointed for this purpose. A. W. Robertson, chairman of the Westinghouse Electric & Manufacturing Company is chairman of the general convention committee.

Electrical Congress to be Held in Paris

The fifth meeting of the International Electrical Congress is to be held July 1932 in Paris, where the first meeting of this congress was held in the year 1881. Subsequent meetings were held in Chicago (1893) Paris (1900) and St. Louis (1904).

The purpose of the 1932 congress is to review developments of the last few years in electrical theory and practise, and to enact such rules and formulate such standards as may be of advantage to future electrical progress.

An American committee on organization has been appointed to arrange for the participation of technical and industrial organizations in the United States, and for the preparation of papers; it will welcome inquiries from persons interested in obtaining further information. The names of those serving follow:

E. W. Rice, chairman, General Elec. Co., Schenectady, N. Y.

G. K. Burgess, Bureau of Standards, Washington, D. C.
James Burke, Burke Elec. Co., Erie, Pa.
L. W. Chubb, Westinghouse E. & M. Co., E. Pittsburgh, Pa.
W. D. Coolidge, General Elec. Co., Schenectady, N. Y.
E. C. Crittenden, Bureau of Standards, Washington, D. C.
W. A. Del Mar, Habirshaw Cable & Wire Corp., Yonkers, N. Y.
Gano Dunn, 43 Exchange Pl., New York, N. Y.
L. L. Elden, Edison Elec. Illum. Co., 39 Boylston St., Boston, Mass.
L. A. Ferguson, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
A. N. Goldsmith, Radio Corp. of America, 570 Lexington Ave., New York, N. Y.
C. E. Harte, The Connecticut Co., New Haven, Conn.
D. C. Jackson, Mass. Inst. of Tech., Cambridge, Mass.
F. B. Jewett, American Tel. & Tel. Co., 195 Broadway, New York.
A. E. Kennelly, Harvard Univ., Cambridge, Mass.
C. O. Mailloux, 111 Fifth Ave., New York, N. Y.
J. H. McGraw, 10th Ave. & 36th St., New York, N. Y.
R. A. Millikan, Calif. Inst. of Tech., Pasadena, Calif.
I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston, Mass.
F. D. Newbury, Westinghouse E. & M. Co., East Pittsburgh, Pa.
H. S. Osborne, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
Farley Osgood, 31 Nassau St., New York, N. Y.
F. W. Peek, Jr., General Elec. Co., Schenectady, N. Y.
Harold Pender, Univ. of Penna., Philadelphia, Pa.
M. I. Pupin, Columbia Univ., New York, N. Y.
L. T. Robinson, General Elec. Co., Schenectady, N. Y.
L. B. Stillwell, 11 West 42nd St., New York, N. Y.
N. W. Storer, Westinghouse E. & M. Co., E. Pittsburgh, Pa.
S. W. Stratton, Mass. Inst. of Tech., Cambridge, Mass.
Philip Torchio, New York Edison Co., 124 E. 15th St., New York, N. Y.
W. R. Whitney, General Elec. Co., Schenectady, N. Y.

Welded Rail Committee Reports Further Progress

Progress Report Number Seven of the Committee on Welded Rail Joints recently was received at A. I. E. E. headquarters from the Institute's representative in that body, Prof. D. D. Ewing (F'20) of Purdue University, Lafayette, Indiana. This report has been filed for reference in the Engineering Societies Library, 29 West 39th Street, New York, N. Y. The committee is sponsored jointly by the American Bureau of Welding (welding research department of the American Welding Society and division of engineering of the National Research Council) the American Electric Railway Engineering Association, and the United States Bureau of Standards. Its membership comprises a total of about 60 individuals, including way engineers of several of the larger street railway companies, representatives of manufacturers of welded joints and welding equipment, welding experts, scientists, and testing experts.

About $24,000 was contributed originally for use of the committee by the American Electric Railway Association, interested manufacturers and a number of the larger street railways. The Railway Association is acting as treasurer for the fund, expenditures being made upon authorization of the executive committee appointed from the membership of the Committee on Welded Rail Joints. The principal objective of the committee is to improve each type of welded rail joint rather than simply to make comparative tests of the relative merits of these joints.

Previous reports (Reports No. 1 to 6 inclusive) indicate past progress made by the committee. The present report includes a study of the heat effects of thermit welds on the adjacent rail material; the effect of preheating and postheating welded specimens and rail joints; additional repeated impact tests of joints; and a study of butt and fishplate joints made with the atomic hydrogen process. The report includes also a study of stresses and distortions due to the heat of welding of low-carbon to high-carbon plates by Prof. T. R. Lawson of Rensselaer Polytechnic Institute, Troy, N. Y., and a discussion of this study by William Spraragen (M'26) of the National Research Council, New York.

Architects Study Simplified Practises

Typical of the service which the division of simplified practise of the National Bureau of Standards is equipped to supply are the simplified practise recommendations which they are now placing in the hands of each member of the American Institute of Architects. This institute has been active in supporting the simplification movement since the government first sponsored this in 1921.

The architect, although a strong individualist, realizes the benefits and savings inherent in simplification and at the same time knows that his individuality and originality of design are not impaired when simplified building materials are specified. It is not intended that simplification should mean standardization but that the industries will voluntarily limit varieties of stock items to those for which there is a constant demand.

Each member architect is being supplied with a complete list of simplified practise recommendations and is being informed of opportunities to obtain complimentary copies of any of the recommendations listed. Similar service for other industries has proved very popular and effective. Edwin W. Ely, chief of the division of simplified practise, states that this same service will be extended upon request to other associations.

Non-Magnetic Watch.—A new nickel-steel alloy originated by Dr. C. E. Guillaume, a winner of the Nobel Award in Physics, permits making a watch with hairspring and balance wheel which cannot be magnetized permanently. The conventional watch with regulation steel hairspring and the usual type of balance wheel becomes so erratic after exposure to magnetic fields up to 360 lines per sq. in. as to be rendered useless as a timekeeper. Extensive tests show that even in a field of 3,600 lines per sq. in. the hairspring and balance wheel of non-magnetically equipped watches were stopped only while actually within the magnetic field, resuming operation immediately upon removal therefrom. Ordinary watches under the same magnetic influence stopped "dead" and would not run again until they had been demagnetized.—*Telegraph and Telephone Age.*

Meeting of Committee on Electrical Insulation.—The fourth annual meeting and conference of the committee on electrical insulation of the division of engineering and industrial research of the National Research Council, will be held at Harvard University, Cambridge, Mass., November 13 and 14, 1931. There will be three technical sessions with papers on the physics and chemistry of dielectrics and on recent progress in engineering research in the field of dielectrics as applied to the insulation of electric circuits. A dinner on Friday evening will be followed by a lecture dealing with recent advances in dielectric theory. Dr. J. B. Whitehead of Johns Hopkins University is chairman of the committee.

South American Congress of Electrical Engineers.—The first congress of electrical engineers in South America is to be held at Buenos Aires from July 4 to 11, 1932, under the auspices of the Asociación Argentina de Electrotécnicos.

School of Welded Building Design.—The opening of a school of welding design at Schenectady, N. Y., has been announced by the General Electric Company. Its purpose is to teach engineers, architects, and draftsmen, both in and out of its employ, the methods of designing welded buildings. The course requires approximately four weeks for completion, and can be adjusted to suit the needs of each individual. There is no charge for instruction, the only requirement being that the applicant be an engineer or have some training in structural design or experience in the design of riveted structures. The differences between the application of welding and riveting to steel frames will be taught. The subject will be approached from a scientific point of view based on studies and tests made by this company over a period of years.

Letters to the Editor

Has Man Benefited by Engineering Progress?

To the Editor:

Permit me to express my complete sympathy with the statements made by Mr. Dreher in his letter published in the September issue (of Electrical Engineering, p. 766) commenting on Doctor Mees's article, "Has Man Benefited by Engineering Progress?" (Electrical Engineering, Aug. 1931, p. 642).

It is well that engineers begin to appraise the advantages of rapid industrial progress as against the importance of the social, intellectual, and spiritual advancement of the human race. It seems that with the growth of mechanical appliances, the necessity for thought has almost disappeared. People go through life controlled by custom, prejudice, and superstition, working for their sustenance at some routine job that requires an infinitesimal amount of brain work and employing the balance of their time in some amusement or recreation that requires still less of intellectual effort.

However, I do not quite agree with Mr. Dreher in his statement that "For all this, engineers are as much to blame as educators, priests, and magistrates." Perhaps the guilt of the educators and magistrates may be comparable to that of the engineers, but surely the greatest blame rests on the priests and other religious leaders who are supposed to lead the way for the social and spiritual advancement of the human race. As Mr. Dreher says, "The inability of men to cast off superstition . . . is fraught with the gravest danger." Probably this inability is due more than anything else to the great power of our present religious leadership, a leadership which is founded entirely on ancient superstitions, to mold public opinion.

Apparently there is among engineers, as among most people, a great fear of antagonizing existing religions, as they are preached by their leaders, and of finding themselves ostracized if they express opinions that seem to run counter to those of the masses, of that "stupid and sadistic herd," to use Mr. Dreher's words. Is it not time for engineers, who are trained from their early youth to learn the truth and to have an open mind, to begin to be frank and outspoken in their valuation of the leaders in other fields?

Only by freeing the human soul and mind from these shackles of prejudice and superstition can we expect the improvement in the social and spiritual life of humanity without which our great mechanical progress is valueless.

It is held quite generally that human nature does not change; I am enough of an optimist to believe that some day our mechanical progress will be considered of less importance than our social progress, and that we shall have leaders in ethics, biology, sociology, psychology, psychiatry, etc., who will convince us that human nature can change for the better; who will show us the way to assist consciously in making this upward progress more rapid. This will be the time when these leaders will be respected and followed to a greater extent than are our modern priests.

There is no reason for not confessing faith in a theory of evolution which has for its goal an ideal human being, possessing within himself, besides the intellectual power that scientific and mechanical progress indicates, a human or spiritual power which will make him realize that only as he can help to improve or enlarge the human values of those with whom he comes in contact can he himself become of greater worth as a member of the human race.

Yours truly,

G. LOBO (A'01, F'12)
(Pres. & Treas., Kelvin Engineering Co., Inc., New York, N. Y.)

Concerning Voice Training

To the Editor:

I wish to offer comment upon some of the statements appearing in "Voice Training on a Scientific Basis," published in the September, 1931, Electrical Engineering:

In order that the experience which may qualify me in making such comment may be known, permit me to say that my hobby is vocal music. Among the various instructors with whom I have studied, I might mention Dan Beddoe, nationally known concert and oratorio tenor, now with the Conservatory of Music of Cincinnati; and Italo Picchi, opera singer, formerly with the Metropolitan Opera Company of New York, now with the College of Music of Cincinnati.

Passing over the first and second paragraphs, which are introductory, the third paragraph I may say agrees precisely with my conceptions based on experience.

The fourth paragraph I also endorse with emphasis. It holds encouragement for the beginner—although some qualification of the statements may be made:

(1) It may be true that in certain cases physiological defects may be present; *e. g.*, a tonsillectomy not carefully done as to restriction in the area of cutting may impair a voice through interference with proper muscular action.

(2) A voice may be inherently not pleasing. I say this with hesitation, for although there is wide variation in individual timber or quality, so much depends upon the mental and emotional characteristics.

(3) Physical vitality is of considerable importance. (While a beautiful rendition of the work of "Violetta" in La Traviata might be made by some one who is "perpetually tired," a robust constitution would be an asset for the singing of the toreador song from Carmen—with encores. Probably it is simply a question of the energy required, both for the tone characteristics and demand upon endurance over a period of time. In other words, the quality of robustness is desirable in a singer; at least for certain work. Average health and vitality, however, are in general adequate, even for professional singing.)

My particular attention, however, has been arrested by the fifth paragraph. I should say definitely that the "lower register" covers the entire range of correct singing. The "register" or manner of tone formation should be uniform throughout the range used, the only difference in tones at different pitch being the naturally increasing pressure of breath as the scale is ascended. (Through exercise of control, lower tones may be sung "forte" and upper tones "piano"—but for a well-developed tone of consistent timber, the natural action will be as first stated.)

The singer's range is about two octaves (instead of three) for a well-developed voice. . . The falsetto or upper register tone is rarely used, and generally is untrained. It is a head tone, usually flat and unpleasing. We say it lacks resonance, but this may be due to inability to produce much vibrato on account of the different use of muscles and resonating cavities. A singer also is usually unable to make much of a crescendo on a falsetto note. Yodelling is the repeated transfer from natural to falsetto tone and the reverse. The falsetto is used by singers of repute occasionally for a pianissimo concluding note in a song, above the singer's natural range.

From a scientific standpoint, I should not take exception to any of the statements in the article except "The registers should be isolated and trained separately; only when fully developed should they be coordinated." From the practical point of view of the singer the value of this opinion is questionable.

I have the opinion that tremolo, or pitch variation, is a fault in singing technique. The author did not clearly define "tremolo;" and the statement that "The vibrato is the means for moving the voice correctly from tone to tone" does not seem to be consistent with his definition of vibrato nor my experience.

Much further scientific work might be done on the human voice, which might include:

(1) The relative contribution as resonators of the various head and throat cavities, and variation in relative volume of sound from nose, mouth, and external surfaces of head and neck.

(2) The possibility of beat notes between resonating cavities resulting in some vibrato without variation of muscular tension, as described in the article.

(3) A study of the transition in tone quality from an "open" to a "covered" tone. Mediocre singers habitually use a tone of one particular timber; the real artist varies the tone quality as well as the intensity and vibrato to suit the emotional interpretation.

(4) A common fault in singers is the incorrect tension of throat and soft, palate muscles. For the individual learning to sing, intelligent tutelage probably will be of more value than a scientific exposition of this subject.

(5) The reduction in range caused by fatigue—particularly the loss of lower notes.

Very truly yours,

CHARLES T. BUTTON (A'29)
(Sales Engineer, Holtzer-Cabot Electric Co., Cincinnati, Ohio)

The Engineer In Civic Affairs

To the Editor:

I was greatly interested in reading the article entitled "The Engineer in Civic Affairs," by J. Allen Johnson in the September issue of ELECTRICAL ENGINEERING (p. 727). The thought occurred to me that I could perhaps add my small bit to the question of solving this problem, due to the fact that I have mixed my engineering work with some public service, having served during my spare time as president of a village board of education for the past eight years, and as chairman of a village planning board for the last five years, during which time I was engaged also as engineer in the design of some of the largest electric power plants in the Metropolitan (New York) district.

Mr. Johnson divides the problem into two questions: (1) how to establish a high professional standing of engineers, and (2) how to establish a high standing of the engineering profession in public affairs.

In answer to question number one I should reply as follows:

It would seem that the rapid strides in engineering achievements during the past generation could not have been possible without the faith of the investing public in providing the necessary financial backing to carry out the ideas advanced by engineers, and the dependence of the public in general upon the skill of the engineer in looking out for public comfort and safety as exemplified in the immediate acceptance and use by the public of new developments as rapidly as they appear.

I should answer question number two as follows:

The question of establishing a high standing for the engineering profession in public affairs rests entirely upon the shoulders of the engineer. If the engineer who may be recognized as an outstanding figure in his profession will refrain from passing judgment on public problems until he has studied and analyzed them in the same manner in which he would attack an engineering problem, and then be prepared to back up his judgment with sound reasoning, the public soon would learn to respect such decisions and thereby bring credit to the profession. The engineer, however, in common with men in other walks of life, likes to have his vanity tickled by being asked questions on public affairs with which he is only remotely familiar, and feels that he must live up to his reputation by answering impromptu. He thereby falls into the trap of making statements, based on snap judgment, which appear ludicrous when broadcast in cold newspaper type.

Only when engineers come to realize that every time a more or less prominent member of their profession passes snap judgment on some outstanding public problem which cannot be solved off-hand, even by persons who have made a long study of such conditions, he thereby brings discredit to the entire profession in the minds of the public, then, and only then, will the necessary steps be taken to correct such conditions so that the profession as a whole can be placed in the position of high standing which it deserves.

As it is desirable that the engineering profession establish a high standing in its opinions on public affairs, the problem of creating such a standing should be attacked at the root. To obtain full and complete information on such problems it is necessary that individual engineers give up a portion of their time to gratuitous public service as suggested by Doctor Wickenden (and quoted by Mr. Johnson). It is only in this way that they can become thoroughly familiar with the thoughts and ideas of the people with regard to public affairs. With this information as a basis on which to work, local councils or committees on public affairs can be formed consisting of representatives of the various engineering organizations who are familiar with such problems through actual contact with the public.

Problems of local interest can be handled readily by these councils, but in order to cover larger problems, the work of the local committees should be coordinated by state-wide councils and, for national problems, through a national engineering council consisting of representatives of all the state councils.

Opinions on public affairs given by such an organization then would not represent the ideas of individual engineers on more or less unfamiliar subjects, but would represent the coordination of the thoughts and ideas of many highly trained minds conversant with the detailed aspects of each case. By means of a flexible organization of this type, consideration of public problems would be confined to the small group interested in local affairs or expanded to cover state or national issues as required to meet the particular case.

In conclusion I should add that in order to secure the confidence of the public in the opinions of the engineering profession in public affairs, there must be a realization among engineers that proficiency and success in their own profession does not of itself qualify them as authorities on public questions which are not of an engineering nature.

Very truly yours,
ROBERT BAKER (A'17)
(Chief Engineer, Thomas E.
Murray, Inc., New York, N. Y.)

A Formula for Happiness

To the Editor:

While the following is perhaps a rather tardy comment on Doctor Mees's refreshing query, "Has man benefited by engineering progress?" (ELECTRICAL ENGINEERING, Aug. 1931, p. 642) it is an immediate discussion on the discussion itself.

Doctor Mees's question was directed to engineers, but the answers so far published have exhibited philosophic elasticity rather than the conciseness one associates with engineering expression. Carl Dreher (ELECTRICAL ENGINEERING, Sept. 1931, p. 766) introduces Schiller into the controversy, and my equally good friend Professor Jansky (ELECTRICAL ENGINEERING, Sept. 1931, p. 766) like Torquemada, would substitute *welfare* for *happiness*. Happiness may be "incommeasurable," but at least it is tangible, intimate, and real, while welfare is often artificial, and arbitrary, with no consistent economic meaning. The Inquisition pinched, burned, racked, and quartered in the fair name of welfare. . . .

The problem is fundamentally hedonistic, and though it cannot be expressed numerically on, engineering principles are violated by the equation:

$$H = \sqrt{\frac{a}{b} - \frac{c}{k}}$$

where the symbols consistently represent emotional factors: H happiness, a the capacity to make the most of potential happiness, b potential happiness, c potential evil, and k the capacity of society to resist evil. History and psychology seem to indicate that over the historical period this last factor has remained constant.

Potential happiness b incontrovertibly has been increased by engineering progress (in the form of) movies, trips around the world, Rolls Royces, private yachts, airplanes, theatres—a thousand luxuries. But it is doubtful if our capacity to enjoy these things a has kept step with their potentiality. On the other hand, potential evil c certainly has received an increment with every major scientific development. Hence, with k a constant, it is probable that the Grecian Helot had not merely "as good a chance" but a better chance "for happiness than most modern factory workers."

It will be observed that if the factor c/k becomes lager than a/b (as necessarily occurs in the case of great economic distress, such as war, depression, strikes and wholesale banditry) happiness H becomes imaginary. And if philosophic considerations must enter into the discussion, inspection of the equation will indicate that the highest attainable happiness is expressed by unity, a mathematical interpretation compatible with Utopian bliss or Schopenhauer's positivity of evil.

Sincerely yours,
ZEH BOUCK (non member)
(Consulting Engineer
Flushing, L. I., New York)

Local Meetings

New York Power Group Opens Season With Talk on Cables

The Power Group of the New York Section will open the 1931-1932 meeting year on the evening of October 6 with a talk on "Power Cables—Development and Trends" by D. M. Simmons, chief consulting engineer of the General Cable Corporation.

Cable engineers have many choices regarding type of cable and insulating materials available for application to specific problems in the transmission and distribution of electricity, and Mr. Simmons will discuss their advantages and disadvantages. He will outline modern trends and show that present developments in the art, undreamed of a few years ago, make practical underground installations up to and including 220 kv. High lights of Mr. Simmons's talk will be emphasized with an interesting group of lantern slides.

In accordance with the established practise of the New York Section groups the meeting will be called promptly at 7:30 p. m. and will adjourn at 9:30 p. m. A cordial invitation is extended to all who wish to join in the discussion. The meeting will be held in Room 1, Fifth Floor, Engineering Societies Building, 33 West 39th Street, New York, N. Y.

New York Communication Group to Resume Activities October 27

The opening meeting of the New York Section's Communication Group will be held on Tuesday, October 27, 1931, at 7:30 p. m. in the auditorium at the Western Union Building, 60 Hudson Street, New York, N. Y. The noted physicist of the Bell Telephone Laboratories, Karl K. Darrow, will discuss "The Flow of Electricity in Various Media." His treatment of the subject will be popular rather than technical and will be of interest not only to men associated with any phase of the communication industry, but also to all members of the Section. Although the meeting will adjourn at 9:30 sharp, there will be ample opportunity for general discussion.

Chicago Section Power Group Organizes for 1931-1932

The Power Group of the Institute's Chicago Section was authorized in 1929 by the Section's executive committee, for the purpose of providing more meetings relating to the generation and distribution of power than were permitted by the limited schedule of formal Section meetings. Meetings of the group since have been held in the rooms of the Western Society of Engineers, with an average attendance of approximately 125; some of these were designated as joint meetings sponsored by that society and the Chicago Section.

L. W. Smith of Sargent & Lundy has been elected chairman of the Power Group for the season 1931-32 and the work will be carried on under the supervision of the executive committee the other members of which are:

F. L. Reinmann, Midland United Co., vice-chairman; A. J. Krupy, Commonwealth Edison Co.; N. O. Pearcy, Byllesby Engg. & Mgt. Corp.; H. T. Eddy, Public Service Co. of Northern Illinois; Gordon Cavanagh, North American Lt. & Pr. Co.

Montana Section Organized

Authority to organize a Montana Section of the Institute with the entire state as its territory was granted at the meeting of the board of directors held June 24, 1931. This Section was organized recently with Bozeman as its headquarters; officers elected are: *chairman*, Prof. J. A. Thaler, Montana State College; *secretary*, H. Dale Cline, Mountain States Telephone & Telegraph Company, Bozeman; *additional members of executive board*, W. A. Boyer, Butte; J. C. Dow, Great Falls; and Rollin Kennard, Great Falls.

Future Section Meetings

Lehigh Valley

October 16, 1931—First meeting of 1931-1932 season. RECENT DEVELOPMENTS IN TRANSFORMERS, by H. V. Putman, manager, transformer engineering department, Westinghouse Elec. & Mfg. Co. Meeting to be held at Altamont Hotel, Hazleton, Pa.

Toledo

October 16, 1931—HIGH TENSION D-C. TRANSMISSION, by H. R. Summerhayes, General Electric Company; ELECTRICAL SYSTEM OPERATION, by F. H. Dubs, Toledo Edison Company.

Past Section Meetings

Portland

SOME INSTITUTE PROBLEMS, by C. E. Skinner, president of the A. I. E. E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co, Also, motion pictures and lecture on Doctor Skinner's trip through the Orient. Dinner at the University Club preceded the meeting. August 18. Attendance 74.

Vancouver

SOME INSTITUTE PROBLEMS, by C. E. Skinner, president of the A. I. E. E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co. Doctor Skinner showed motion pictures which he had taken during his recent world tour. Dinner at the Georgia Hotel preceded the meeting. August 14. Attendance 33.

Personal

H. H. BARNES (F'13) of the General Electric Company, New York, N. Y., recently has been appointed a divisional chairman of the commerce and industry division of the Emergency Unemployment Relief Committee of New York City. Mr. Barnes will head the activities of the electrical industries in the division and will form a committee to conduct solicitations among individuals and corporations in the electrical field. The relief committee has been organized by business leaders to provide for New York's unemployed during the coming winter, and plans for coordinating the task of raising and distributing funds already have been announced.

L. M. CARGO (A'06) executive representative, Mountain States, Westinghouse Elec. & Mfg. Company, Denver, Colo., and recently elected president of the Electrical League of Colorado, was chosen a member of the League Council at the annual conference of electrical league managers held July 27-31, 1931 at Association Island, New York.

A. C. STREAMER (A'10) for some years assistant director of sales, Westinghouse Elec. & Mfg. Company, East Pittsburgh, Pa., has been appointed sales manager of the company's diversified products department in which is grouped all Westinghouse equipment not specifically alined with transportation, central station or industrial activities.

W. S. MOODY (A'06, F'12) consulting electrical engineer transformer department, Pittsfield, Mass. and for 43 years identified with transformer design and production for the General Electric Company, retired as of July 1, 1931, from active work. He however will retain in consulting capacity his connection with the company.

W. S. GIFFORD (A'16) president of the American Telephone & Telegraph Company, New York, N. Y., and director of President Hoover's unemployment relief organization, has been elected to membership on the finance committee of the United States Steel Corporation to succeed the late George F. Baker.

Henry G. Wood (A'23–M'28) assistant manager of the northeastern division of Westinghouse Elec. & Mfg. Company, New York, N. Y. recently changed to become electrical engineer in the general sales department of the Worthington Pump and Machinery Corporation, Harrison, N. J.

A. D. Stephanus (M'28) special representative of Westinghouse Electric International Company, Oslo, Norway, a short time since removed to the company's London office, 2 Norfolk Street, Strand, London W. C. 2, England.

William Shuler (A'15–M'24) until recently electrical engineer for the Columbia Engineering & Management Corporation, Cincinnati, Ohio, has accepted a position with the Dayton Power and Light Company of Dayton, Ohio.

H. E. Stafford (A'13–M'25) electrical engineer, Provincial Paper Mills, Ltd., Port Arthur, Ont., Canada, has changed his position to one with Moss Mines, Ltd., Tip Top Spur, Canadian National Railways, Ont., Canada.

Theodore Bodde (A'19) of the engineering department of the General Railway Signal Company, Rochester, N. Y., has received appointment to professorship at Northeastern University, Mudken, China.

W. P. Hammond (M'20) engineer of generating plants, Allied Engineers, Inc., Birmingham, Ala., has been appointed engineer for the Atlantic district of his company, to succeed L. N. Blagoveschensky.

M. A. Thomas (A'31) who previously has been located at the University of Texas, now is connected with the New Mexico College of A. & M. in the capacity of assistant professor of electrical engineering.

H. S. Evans (A'08) who was manager of the industrial department, Denver division of the Vacuum Oil Company, Incorporated, has removed to the New York headquarters of the company.

I. K. Dortort (A'29) until recently electrical engineer at Camden, N. J. for the Brown Boveri Company, has removed to Milwaukee, Wis., to join the Allis-Chalmers Mfg. Company.

Robert Landis (A'22) designing engineer at Brown Boveri Company's Camden (N. J.) plant now has joined the Allis-Chalmers Mfg. Company at Milwaukee, Wis.

H. Winograd (A'26) electrical engineer for the Brown Boveri Company, Camden, N. J., now is identified with the Allis-Chalmers Mfg. Company, Milwaukee, Wis.

Leo N. Blagoveschensky (A'25) who has been serving in the capacity of district engineer of Allied Engineers, Inc., Atlanta, Ga., has resigned from this position.

Obituary

Harry Phillips Davis (A'01, M'01) vice-president and director of the Westinghouse Electric and Manufacturing Company, chairman of the National Broadcasting Company, and one of the country's foremost engineers and executives, died at his home in Pittsburgh, Pa., September 10, 1931. He had been ill for several months, and at the time of his death was sixty-three years old. He was born at Somersworth, N. H., and was graduated with the degree of bachelor of science from Worcester Polytechnic Institute, from which in 1930 he received also the honorary degree of Doctor of Engineering. For more than 21 of the 40 years he was connected with the Westinghouse Company, he had charge of the company's engineering department; for 15 years, he directed its engineering and manufacturing operations. In 1911 he was elected a vice-president. Among his early achievements was his work in the electrification of the New York, New Haven and Hartford Railroad, the world's first single-phase railway electrification and a phenomenal engineering feat. His ability penetrated not only all phases of this electrification but many others that followed it. He was a man of indomitable energy, initiative, and vision, and his career was one of wide achievement. Nearly eighty electrical patents have been issued to him, and under his leadership many of the most important advances in the electrical art relating to meters, measuring instruments, circuit breakers, railway control, transmission, and radio, have been made. His foresight was perhaps most clearly demonstrated in the starting of the first broadcasting station; at a time when the public, and engineers as well, were looking upon radio quite definitely as a means of private or point-to-point communication, Mr. Davis envisioned it as a public service over a wide area and one to which everyone might listen. That was the birth of radio broadcasting, and by Mr. Davis it was looked upon as a public trust. With the success of the first station, November 2, 1920, he quickly placed others in service, thus establishing what may well be termed one of the greatest developments of the century. He was active in every phase of radio, and at the time of his death was known internationally as the "father of radio broadcasting."

Mr. Davis was director of more than a dozen corporations, among them the Westinghouse Electric International Company, Automatic Gear Shift Company, the Radio Corporation of America, R. C. A. Photophone, Inc., Radio-Keith-Orpheum Corporation, R. C. A.-Victor Company, Inc. He was also a vice-president of the Turtle Creek & Allegheny Railroad Company, and held membership in many engineering and scientific societies, the University Club of Pittsburgh, the Pittsburgh Athletic Association, and the Oakmont and Edgewood Country Clubs.

Edward James Condon (A'12, M'21) president of the Condon Engineering Company and General Power Company of Chicago, Ill., died suddenly August 25, 1931, of heart disease. He was 69 years old, having been born in Cambridge, Mass., and educated in the Boston public schools. He first became interested in engineering and utility work in 1893, and in association with several others accomplished a number of water and sewer contracts for the city of Chicago. In 1896 he directed the building of a reservoir on the southern slope of Pike's Peak for the city of Cripple Creek, Colo. The following year he returned to Chicago as a member of the firm of Cleary & Company, doing municipal work constructing water works, and gas and electric plants. As early as 1905 he became interested in several small electric plants, rebuilding some of them into an interconnected system in northeastern Indiana and southern Michigan. In 1924 these latter properties were bought by the Midland Utilities Company. Concurrent with his ownership and management of the Condon Engineering Company, he became president, general manager, and part owner of the Minnesota Electric Light & Power Company and the Eastern Montana Light & Power Company; still later he was elected to the vice-presidency and general management of the Inter-Mountain Railway, Light & Power Company, operating in sixty cities and towns in twelve states. In 1925 he became president of the General Power & Light Company, but in 1929 disposed of all of his utilities properties and devoting his entire time to the Condon Engineering Company. His friendly personality won for him a wide acquaintance, not only among the men of all ranks in professional and the utility fields, but in fraternal organizations as well. He was a past-president of the Indiana Electric Light Association. He was always active at technical conventions; and was a member of the Western Society of Engineers, the Art Institute (Chicago), and Knights of Columbus.

Edward Otto Zwietusch (A'22) general manager of C. Lorenz A. G., was killed in an automobile accident August 8, 1931. To German industry his death represents the loss of an exceptional organizer. An American by birth (Milwaukee), January 20, 1866) he attended the University of Wisconsin at Madison. In 1886 he entered the employ of the Western Electric Company, and there received a practical knowledge of telephony, then in its infancy. This knowledge he utilized by going to Berlin in 1888 and founding the Telephon-Apparat-Fabrik. In untiring effort, he invented many new methods of telephony which were immediately adopted by the Reichspost. Charmed with the country of his ancesters, Mr. Zwietusch in 1904 became a German citizen, until 1921 conducting his business in Salzufer; then he became the representative of the Western Electric Company with the International Standard Electric Corporation, a position which he held until 1926. In January 1927 he was appointed General Director of the Vereinigten Telephon und Telegraphenfabrik, A. G. Czeija, Nissk & Company, Vienna. At the completion of this work early in 1930 he undertook the management of the Telephonfabrik Berliner A. G. in Berlin-Steglitz, remaining until accepting his recent position. Mr. Zwietusch was a man of few words, but he studied every problem thoroughly not only from a theoretical point of view, but a practical business angle as well. He was a man much beloved by his co-workers and esteemed by all with whom he had business dealings.

Donald Fairfax Whiting (A'18, F'30) since January 1930 technical director and chief engineer of the Fox Hearst Corporation of New York City was killed in an accident on September 8, 1931. He was born in Lowell, Mass., April 13, 1891, and graduated from Worcester Polytechnic Institute in 1915, receiving his E. E. degree in 1922. He was licensed as an electrical engineer by the University of the State of New York in 1927. In 1916 he entered the special research department of the Western Electric company, and in 1925 was made supervisor of the apparatus development department of the Bell Telephone Laboratories. Two years later he became staff engineer in charge of testing and research for the Fox Hearst Corporation and in 1929 was promoted to direction of the work. In each of these affiliations, Mr. Whiting evidenced rare inventive genius. He was a member of the Institute of Radio Engineers and of the Society of Motion Picture Engineers; and a fellow of the Radio Club of America and of the American Association for the Advancement of Science. At the time of his death he was still active on the following committees: membership, Radio Club of America; papers, Radio Club of America; projection, Society of Motion Picture Engineers; and committee on standardization of the Institute of Radio Engineers.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Balaguer, Manuel M., c/o International Tel. & Tel. Co., 67 Broad St., New York, N. Y.

Bunce, Lewis I., Rocky Hill, Conn.

Clark, Bernard, 79 Jenness St., East Springfield, Mass.

Cole, Will G., Box 222, Westwood, Calif.

Farnlof, Charles G. T., 1318 Laketon Road, Wilkinsburg, Pa.

McLean, James S., 190 Old Army Road, Scarsdale, N. Y.

Melson, Sydney W., Yeatton Woolwich Road, Abbey Wood, London, S. E. 2, England.

Mountain, C. E., Burma Elec. Supply Co., Mandalay, Burma, India.

Parr, J. C., 245-71st Street, Brooklyn, N. Y.

Pistorius, L. H., 193 Jeppe St., Johannesburg, South Africa.

Prudham, W. M., 100 Biddle St., Wilkinsburg, Pa.

Schrock, John E., 3720 Main St., Lawrence Park, Erie, Pa.

Stempfle, Frederick, 8126 E. Vernor Highway, Detroit, Mich.

Tate, William, Apartado No. 41, Publa, Mexico.

Voronovsky, T. G., 1162 Waverly Place, Schenectady, N. Y.

Test Code for Transformers

In the early part of 1929 a proposition was placed before the standards committee of the Institute, looking to the development of test codes for electrical machinery and apparatus. After a careful survey to obtain the reactions of key men in the manufacturing and electric power fields, the committee decided to proceed, covering for the time only the development of codes for the more important types of apparatus, such as generators, motors and transformers. This procedure was approved by the board of directors in May 1929. The standards committee then asked the electrical machinery committee to undertake the work, and at the meeting of July 23, 1931, the first report from the electrical machinery committee covering the "Test Code for Transformers" was received.

In order that the electrical industry might become fully cognizant of the work undertaken and at the same time be given a clear picture of just what it was contemplated to include in such test codes, the standards committee recommended to the board of directors that the "Test Code for Transformers" be made available to industry as a pamphlet published under the auspices of the electrical machinery committee. This suggestion was approved at the directors' August meeting, and the work of publication is now under way. Notice of the availability of the pamphlet will appear in a later issue of Electrical Engineering.

Engineering Foundation

Bequest of Edwin H. McHenry

United Engineering Trustees, Inc., has been made residuary legatee of the estate of Edwin H. McHenry of Ardmore, Pa. The estate is believed to amount to $225,000. Mr. McHenry died August 21, 1931. He was a member of the American Society of Civil Engineers. At one time he was receiver of the Northern Pacific Railway Company, and vice-president of the New York, New Haven & Hartford Railroad at the time when the electrification between New York and New Haven was undertaken; later he carried on a consulting practise. During his connection with the Northern Pacific Railway he was associated with the late Edward Dean Adams, through whose influence he made a small provision in his will for The Engineering Foundation. This he later changed to provide essentially that United Engineering Trustees, Inc. should receive the entire estate after the death of four beneficiaries who are to receive the income of the estate during their lives. Upon their decease, the entire principal of the trust estate is to be conveyed absolutely in fee to United Engineering Trustees, Inc. for The Engineering Foundation. Mr. McHenry makes this fund for research a memorial to his wife, Blanche H. McHenry, who died some years ago.

Standards

Several Projects Referred to New Committee

During July, approval of the new electrical standards committee was obtained from the eleven organizations of which it will be composed. This new committee supersedes the present electrical advisory committee of the American Standards Association, and will serve as a central agency in furthering the standardization work of the electrical industry. To this end all methods of procedure now recognized by A. S. A., as well as all powers for the formulation of standards, have been concentrated into one body, a new development initiated by the A. I. E. E. Resolutions transmitting it to A. S. A. were approved in January 1930 by the Institute's board of directors; steps are now under way for consolidating the work of the new committee with that of the U. S. national committee of the International Electrotechnical Commission. Detailed statement of this new development in electrical standardization was included in the August 1931 issue of the Bulletin of the A. S. A. which is obtainable from P. G. Agnew, secretary, A. S. A., 29 West 39th Street, New York, N. Y.

At the July 23rd meeting of the A. I. E. E. standards committee, action was taken recommending that several standards projects be referred to the new committee for disposition. These actions, subsequently confirmed by the board of directors, were:

1. Report No. 16, Railway Control Apparatus. This is a proposed revision of the present Institute and American standard on the same subject.

2. Standard N . 13, Transformers, Induction Regulators and Reactors. This is an Institute standard only, and reference was accompanied by suggested revisions.

3. Pamphlet No. 100, Recommendations for the Operation of Transformers.

4. Sixty-cycle Test Voltage for Transformers. This matter has been before the electrical machinery committee and there is a difference of opinion regarding its proper disposition.

5. Standard No. 12, Constant-Current Transformers, an A. I. E. E. standard since May 1930.

6. Report No. 18, Capacitors. Since May 1930 this has been a report on a proposed standard.

American Standards for Wood Poles Approved

For some time a sectional committee under the sponsorship of the telephone group of the American Standards Association and representing 23 organizations including the A. I. E. E., has been at work on the development of standards for wood poles. Already eight such standards have received the approval of the A. S. A., each standard covering ten classes of poles. These standards are available in four pamphlets dealing respectively with dimensions and specifications of (1) northern white cedar poles, (2) western red cedar poles, (3) chestnut poles, and (4) southern pine poles. These pamphlets are available at 20 cents per copy from the American Standards Association, 29 West 39th Street, New York, N. Y.

Relay Standards Report Available

A pamphlet, "Report on Standards for Relays" (A. I. E. E. standards report No. 23) is now available for suggestion and criticism. This report was prepared by a subcommittee of the A. I. E. E. standards committee under the chairmanship of George Sutherland of the New York & Queens Electric Light and Power Company; copies may be obtained free of charge from H. E. Farrer, secretary, Standards Committee, A. I. E. E., 33 West 39th Street, New York, N. Y.

The report deals with relays and relaying devices for the protection and control of apparatus and circuits for the generation, transmission, conversion, distribution and utilization of electric power. It does not include telephone, telegraph, traffic signal relays, or similar devices. The subjects covered are: service conditions, definitions, ratings, heating, limitations other than heating, dielectric tests.

New Standard Regulations for Signaling Systems

On recommendation of the National Fire Protection Association's committee on signaling systems, the regulations on protective signaling systems have been revised and divided into two separate pamphlets. The new regulations became effective September 15, 1931, displacing the former regulations on protective signaling systems, edition of 1929. The new pamphlets cover regulations for the installation, maintenance, and use of "Proprietary Auxiliary and Local Systems for Watchman, Fire Alarm, and Supervisory Service," and "Central Station Protective Signaling Systems for Watchman, Fire Alarm, and Supervisory Service." For further information and copies of pamphlets, address National Board of Fire Underwriters, 85 John Street, New York, N. Y.

Safety Code for Coal Mine Transportation

A safety code covering all phases of coal mine transportation recently has been approved by the American Standards Association as recommended American practise. The code deals with transportation on level and inclined tracks both underground and in mine yards; also haulage by motors, animals, or men. Complete systems of signals and safety rules are included. This work carried on under the sponsorship of the American Mining Congress has been in progress since 1924. Orders for the code may be placed with the American Standards Association, 29 West 39th Street, New York, N. Y.

New National Safety Code for Elevators

A new national safety code for elevators, dumbwaiters and escalators, recently has been approved by the American Standards Association. Developed under the sponsorship of the American Society of Mechanical Engineers, the American Institute of Architects and the U. S. Bureau of Standards, the revised code represents the result of nearly four years of research. For the first time, the code permits the operation of more than one elevator in a single shaft and also, provides for two-story cars serving two floors simultaneously. All communications relative to the code should be addressed to the American Standards Association, 29 West 39th Street, New York, N. Y.

Employment Notes

Of the Engineering Societies Employment Service

Position Available

SALES ENGINEER, 21 or 22, unmarried, to act as office engineer and secretary with manufacturers' agents sales office selling transmission and high-tension equipment for the New England States. Apply by letter giving complete information as to past experience, references and salary expected. Location, Boston. W-3080.

Men Available

TECHNICAL GRADUATE, 21, B. S. in E. E., 1931. Interested primarily in position offering stability, opportunity. Licensed broadcast class radio operator; two years' experience, operation and maintenance at 5-kw. station and general radio communication work. Prefers radio, telephone communication fields with work in laboratory, engineering department. Location, immaterial. Available immediately. C-9725.

ELECTRICAL ENGINEER, technical graduate, G. E. Test. Over 18 years' experience, including electrical manufacture; railway construction, valuation and maintenance; power line construction and steam railroad electrification. Desires position with company doing consultation and construction engineering or with operating company. B-7456.

GRADUATE ENGINEER, 22, single, B. S. in E. E., 1931. Two years' experience with public utilities in distribution and grounding work. Location, immaterial. C-9739.

ELECTRICAL-CIVIL ENGINEER, 27, married, university graduate. Desires position anywhere with public utility or contractor. Three years as sales and service engineer for electrical machinery manufacturer, specializing in synchronous equipment. One year as electrician on station construction. Two years varied civil engineering, including compressed air and rock-tunnel construction. C-4885.

ELECTRICAL AND CHEMICAL ENGINEER, 43, A. B. and B. S., executive experience in manufacturing and research; also public relations. Very successful in combating adverse publicity. Considerable experience in study of toxic gases. Available immediately. B-200.

COLLEGE GRADUATE, 23, single, B. S. in E. E., 1931. Desires work. Best of references. C-9747.

GRADUATE ELECTRICAL ENGINEER, 22, single, Lehigh University, 1930. Nine months' experience in the plant department of the American Telephone and Telegraph Company. Desires position with manufacturing concern or public utility. References furnished on request. Location, immaterial. C-9748.

PATENT ATTORNEY, 37, mechanical electrical engineer, independent reliable worker, broad, domestic, foreign experience acquired in research, industrial teaching, responsible engineering positions, five years with corporation patent department, now almost three years with large patent law firm, versed in foreign languages, growing clientele, desires connection with firm, attorney seeking competent intelligent cooperation. References available. C-9762.

RELAY AND CONTROL ENGINEER, 30, graduate McGill, location, Canada. Experienced planning protective circuits, automatic and supervisory controls. Familiar with equipment of generating stations, use of laboratory facilities and field engineering methods. Experienced on communication, amplifiers, photoelectric cells and maintenance of highest standards in associated circuits. Proven ability in personal contact. C-4668.

DESIGN ENGINEER, 27, technical graduate, 7 years' experience. Desires position with manufacturing firm. Experience covers: power station and substation design, production design of radio accessories, machine and tool, cemented tungsten-carbide development, power and conveyor equipment of nitrate plant. Good theoretical and practical background. Location, East. Available at once. C-4382.

GRADUATE ELECTRICAL ENGINEER, 33, married, B. S. in E. E. Eight years' experience in engineering work. Supervising design and construction of plant distribution, economic studies and cost estimating, public utility. Also sales engineering and contact work for manufacturing concern. Desires position with manufacturer, industrial concern or public utility. Location, United States. B-5858.

ELECTRICAL DESIGNER, 38, married. Fourteen years' public utility experience, five different corporations, power plant, switching station, substation, both indoor and outdoor. Desires connection with public utility or industrial organization. Available now. Location preferred, East. C-8490.

ELECTRICAL ENGINEER, graduate Georgia Tech., 1930, cooperative plan. Westinghouse lighting courses. Cooperative work, alternate months, five years in substation maintenance and office engineering. Rebuilding transformers, switches, lightning arresters, work with electric furnaces, rectifiers, meters, motors, etc. Checking and mapping distribution systems, work orders, drafting, etc. Excellent references. Perfect health. Location, immaterial. C-7847.

GRADUATE ELECTRICAL ENGINEER, 38, married. Sixteen years' experience in electrical engineering work. Central station design and specification. Light, power and signal systems for commercial and industrial buildings. Investigations, reports, design, layout, specifications, construction, inspection. Desires permanent position as electrical engineer with good opportunities for advancement. Connecticut or New York. B-1797.

ELECTRICAL ENGINEER, 31, married, no children, B. S. degree in 1923, working knowledge of Spanish. Over seven years' varied experience in planning, estimating, construction and operation of distribution and transmission systems. Location, immaterial. Available at once. C-9711.

ELECTRICAL ENGINEER, 32, married, Wisconsin graduate, construction, shop and seven years' power plant design experience. Available on short notice. C-9797.

EXECUTIVE ENGINEER, 40, graduate engineer, with ability to supervise and to create good-will and increase business through contacting and publicity. Would be valuable to electrical organization or organization serving the electrical industry. Has wide knowledge of industries and large acquaintance with engineers. C-9067.

ELECTRIC FURNACE PLANT MANAGER, mechanical engineer, abrasive and refractory experience. Engineering executive and designer. Expert in fluid flows and heat transfer problems. Analytical and inventive ability. Opportunity to secure experienced manager for small or branch plant. B-7972.

HYDROELECTRIC ENGINEER, 47, single. Degree Ph. B. in E. E., two years U. S. engineer. Ten years utility service as department manager, superintendent and chief engineer. Ten years Westinghouse industrial manager; five years electric dredging Alaska. Reports. Central America. Export manager Westinghouse two years. Available to go anywhere. B-6910.

ELECTRICAL ENGINEER, 44, married, B. S., E. E. Two years G. E. Test, eleven years motor applications; seven years with public utilities making variety of studies including transmission line, cable calculations, synchronous condenser applications, short circuit, load studies on d-c. calculating board, special research problems involving protective equipment. Location, United States. C-9811.

ENGINEERING DRAFTSMAN, 25, single, 2 years university training, 3 years' experience on power transmission lines, telephone work, and water resources. One year's experience as field aid. Available now. Will go anywhere. C-7118.

PLANNING ENGINEER, 31. Ten years' electrical-mechanical experience. Comprehensive knowledge coil, transformer, industrial meters and precision instrument design. Well versed in manufacturing methods, development, and cost reduction studies. Specialist in automatic control of processes, also general plant generation, transmission, distribution. Now employed. Accept position home or abroad. C-7258.

MECHANICAL-ELECTRICAL ENGINEER, 33, married. Graduate of recognized engineering school. Experienced in power generation. Five years teaching electrical and mechanical engineering. Heat power and specialty. High-voltage test. Extensive water gas research. Division engineer of water gas and coke ovens. Desires connection in teaching, public utility or industrial fields. Available immediately. C-9776.

ELECTRICAL ENGINEER, 33, married, B. S. in E. E. Ten years' experience as engineer with utility company. Familiar with design of lines and stations; accounting set-ups; executive duties and powers; modern business practise and now studying corporation law. Available at once. C-4734.

ELECTRICAL ENGINEER, 22, single, B. E. E. degree, 1931. Three years with Boston Edison Company, maintenance department on cooperative course. Temporarily employed last summer repairing Frigidaire cabinets for an ice cream company. Desires position offering some contact with engineering work. Location, anywhere. Available on two weeks' notice. C-9418.

GRADUATE ELECTRICAL ENGINEER, 27, single. Seven years' experience in supervising and laying out of electrical construction work in various industrial plants and buildings. Desires position as superintendent or electrical engineer with a contracting or industrial firm or municipality. Available at once. C-9553.

ELECTRICAL FOREMAN, 31, broad experience in power plant and factory construction, maintenance and operation. Exceptional ability in the erection and wiring of switchboards, power plant auxiliaries, oil circuit breakers and high-voltage substations. Available immediately. C-9783.

RECENT GRADUATE, age 21, single, citizen, good health, Protestant, B. E. E. degree, drafting and clerical experience, organization work. Would like to locate with a firm dealing with illumination of radio. Location, East. C-9756.

ELECTRICAL ENGINEERING GRADUATE, Columbia, 1931. Six-year man, single. Desires position with public utility or manufacturing concern. Studied especially power field, railroading and business administration. Experienced on automotive engines. Has acted as laboratory assistant in elementary E. E. courses. Languages: German and Spanish. Location, immaterial. Available immediately. C-9788.

RESEARCH PHYSICIST, 39, Ph. D., five years with Westinghouse on radio, television, sound recording and reproduction, four years bureau of standards and other government bureaus on optical design, heat engineering, also refrigeration experience, four years' teaching in prominent engineering schools, seeks responsible position in research or design. C-2588.

ELECTRICAL ENGINEER, 22, B. S.-E. E., 1930. Desires connection with public utility, electrical or radio manufacturing company. General Electric test experience. Six months' work with vacuum tubes. Experience with large motors. Location, immaterial. C-9806.

WIRING DIAGRAM SPECIALIST, 43, married, technical education, desires position with public utility. Understands cooperation necessary between office and field forces in connection with wirings. Familiar with powerhouse and substation layouts, conduit plans, bus structures, switchboards. Experienced in drafting and its application to field work. Location preferred East or South. C-8436.

ELECTRICAL ENGINEER, 36, single, E. E. degree. Desires position with public utility or engineering concern requiring executive ability and an analytical mind. Fourteen years' experience covering engineering, design and valuation of power plants, substations, transmission and distributions systems. Available immediately. Location, East. C-9570.

1931 GRADUATE of five-year cooperative school in electrical engineering. E. E. degree, age 23, single. Cooperative experience includes machine shop practise, telephone central office trouble shooting and experience with large municipal fire alarm system. Desires position with manufacturing concern or public utility. Willing to start at bottom. Location, Middlewest, preferred, but elsewhere satisfactory. C-9825.

ELECTRICAL ENGINEER, 29, single university graduate, Norwegian, now located in Canada. Five years' practical experience on drafting, designing, calculation, maintenance and testing for electrical machinery and equipment, substations, power transmissions, municipal and industrial distribution. Location, immaterial. Available on short notice. C-9822.

ELECTRICAL ENGINEER, 32, married, B. S. in E. E., graduate G. E. Test course, 3 years' practical experience light and power wiring, 3 years drafting, inspection, and installation of bank burglar alarm equipment. Desires position with electrical contracting company or bank burglar alarm company. B-8209.

TECHNICAL GRADUATE in mechanical and electrical engineering. Desires position as assistant sales engineer in electrical or mechanical equipment. Age 32, single, with ten years' experience in electrical and mechanical design and sales. Available at once. C-4510.

1931 GRADUATE ELECTRICAL ENGINEER, 29, 3 years' cooperative experience with large eastern public utility, single now, married when permanent position obtained. Desires position with utility, manufacturer or contractor. C-9834.

ELECTRICAL ENGINEER, 24, single, Iowa State College, 1931. Experience limited. Desires employment with public utility or manufacturing concern. Salary secondary to opportunity. Available at once. Location anywhere in the United States. C-9827.

ELECTRICAL ENGINEER, 30, married, B. S. in M. E. 1924, one year instructor of drawing and descriptive geometry in university. Six years design, construction of power plants, power substations, mining substations. Six months Westinghouse Test Course. Desires position as professor, instructor of design, electrical construction in university, technical school, Location, secondary. C-5734.

PRODUCTION OR EFFICIENCY ENGINEER, 26, E. E. graduate, 1929. Business administration. G. E. Test. Machine experience, turret lathes, boring mills, drills, millers, etc., automobile industry. Thoroughly familiar, tube rolling mill operations and processes. Distribution engineering, a-c. networks, electric utility. Private generating plants, studies and estimates on cost of retirement. Any location. C-9820.

GRADUATE ELECTRICAL ENGINEER, age 28, married, with years' experience in industrial plant construction and maintenance; railway electrification; power plant design, estimating, and construction. Supervisory experience on construction and costs with contractor. Desires position with utility, manufacturer or contractor, where ability to handle labor and produce results is a prerequisite. C-4428.

GRADUATE ELECTRICAL ENGINEER, University of Wisconsin, 32, single. Three years Westinghouse Test. Seven years supervising power plant, substation transmisson line construction. Eight years engineer inspector, purchasing, expediting, resident engineer, and writing specifications. Excellent reference. Desires connection with holding company, utility, contractor or manufacturer. Available immediately. Location, immaterial. B-9661.

ELECTRICAL ENGINEERING ASSISTANT, 26, married, college graduate, four years' transmission and distribution experience with public utilities on design, estimates, survey and evaluation. Desires connection with public utility engineering department. New York city location preferred, but will consider any United States location. C-5511.

GRADUATE ELECTRICAL ENGINEER, 1930, single. One year's experience on test, design and development of small fractional and integral horsepower motors. Previous experience with public utilities. Now employed. Position must be permanent and promise a good future. Location a secondary factor. C-9590.

DESIGNING ENGINEER, 33, American, technical education, married, experience with industrial, mining and public utility companies, on power plants, steam and Diesel installations, including all auxiliaries, air conditioning and ventilating systems, automatic railway substations, outdoor substations, ability to requisition equipment, knowledge of steel, and concrete, can handle men. Location, immaterial. C-9849.

ELECTRICAL ENGINEER, 1930 graduate, 23, single. Fourteen months General Electric Test. Experience in automatic switchgear; circuit breakers; railroad motors, control, and locomotives; power rectifiers; synchronous converters, condensers, and motors; large motors, generators; transformers and variable speed a-c. machinery; calculating stability of transmission lines. Desires position in engineering field. Location, immaterial. C-9841.

ELECTRICAL ENGINEER, 22, single, B. S. E. E. 1931, from Pennsylvania State College, available on reasonable notice. One year's experience with silk-mill equipment, three months in transmission department of public utility, two semesters' motor tests in college. Desires position with utility, engineering or manufacturing company. Location, U. S., East preferred. C-9850.

MECHANICAL AND ELECTRICAL ENGINEER, research, development, reports, physical tests of materials, metallography, X-ray analysis. Languages: French and German. Available on short notice. Location immaterial. C-6094.

GRADUATE ELECTRICAL ENGINEER, 1929, 23, single; 15 months on G. E. Test Course. Desires position with utility or manufacturing company or with concern doing consulting or construction engineering. Available immediately. Location, New England preferred. C-8028.

ELECTRICAL ENGINEER, college graduate, age 23, married. Considerable experience in service and testing of fractional horsepower motors. Laboratory assistant and construction work while at college. Desires opening with advancement and opportunities. Available two weeks' notice. C-9084.

ENGINEER, 42, married; B. S. and E. E. Broad experience covering business, plant, sales management; executive engineering; research; drafting; patent investigations; organization and coordination of departments; assistant to busy executives; group engineering leadership; design and manufacture electrical and radio equipment. One employer sixteen years. Traveled extensively on business United States and abroad. C-9804.

INDUSTRIAL ELECTRICAL ENGINEERING GRADUATE, 1931, Pratt Institute, 23, single. Additional course taken in motor control. Four years' experience; power and lighting installation; servicing motors and control equipment. Some mechanical experience. Desires position with utility company; concern doing consulting or construction engineering or related work with manufacturing concern. C-9856.

DISTRIBUTION SUPERINTENDENT, 45, single. Graduate civil engineering. Two years transmission line surveying. Four years designing overhead lines, rural extensions, conversion from 2,300 to 4,000 volts. One year designing complete distribution systems in South America. One year superintendent operating company. Fluent Spanish, some French, German, Italian. C-2495.

ELECTRICAL ENGINEER, technical graduate, 31, married, desires position in electrical engineering field. Five years' experience in plant and substation construction, operation, maintenance and repairs; switchboard erection; motor and centrifugal pump installation and maintenance; inspection of electrical equipment. Location preferred, eastern United States. C-6273.

ELECTRICAL ENGINEER, graduate 1928, age 27, married. Has over two and one-half years' industrial testing experience, particularly in motor and control; also civil engineering and supervisory experience. Not afraid of responsibility. Desires a position with a future. Location immaterial. C-9568.

ELECTRICAL ENGINEER, age 32, married. Six years' experience with large manufacturer, on testing; design of a-c. machines, general and application engineering, and sales on power generation and transmission equipment. Three years' experience consulting and planning engineer for utilities. Desires connection with utility or manufacturer. Location immaterial. C-9814.

ELECTRICAL ENGINEER, 23, B. S. in E. E., University of New Hampshire, 1930. Fourteen months G. E. Test and general course. Test experience in transportation, motors and generators and vacuum tubes. Nine months summer work in main line electric railway shops. Interested in any engineering work. Available short notice. C-9859.

ELECTRICAL ENGINEER, technical graduate, American, age 29, married. Three years power test with G. E. and utility company. Three years research and development on electrical equipment. More interested in permanent connection with reliable concern than high starting salary. Eastern location preferred. Available immediately. C-1017.

GRADUATE ELECTRICAL ENGINEER, B. E. E. Degree 1930, age 24, single. Fourteen months' experience in the layout and estimation of underground network in a large city. Three months substation maintenance. Desires transmission line or distribution system work. Middlewest preferred. C-9860.

ELECTRICAL ENGINEER, 21, single; 1931 graduate with B. S. in E. E. Member of honorary fraternity in college and won scholarship three consecutive years. Summer experience with public utility. Interested in any electrical engineering field including vacuum tube work. Available at once. Location, New York preferred but not essential. C-9467.

PHYSICIST, 40, married; experienced in X-ray, radium and high frequency, desires position in electrical research. C-8604.

ELECTRICAL ENGINEER, graduate, 1929, cooperative school, American, Protestant, 31, married. Three years design, engineering, appraisal. Six years electrical construction, generating station and substation power company. Wishes position with public utility as junior engineer or in research laboratory. Will go anywhere, United States. Available now. Unemployed. C-9861.

GRADUATE ENGINEER, Stevens Institute of Technology, 1931, single, 22, available immediately. Desires position in any electrical line with opportunity for advancement. Location, immaterial. C-9473.

MECHANICAL AND ELECTRICAL ENGINEER, married; degrees here, and Doctor, Germany for research. Fifteen years connected and in charge purchasing, sales and export office handling materials every possible description in large amounts. Wide business experience. Linguist. Adaptable to any position outside those mentioned. C-7823.

ELECTRICAL ENGINEER, 26, single, 1928 graduate of recognized university with B. E. E. degree; four years' engineering experience; including 20 months on large electrified railroad, one year public utility test experience, one year communication and radio experience. Desires engineering position. Free to locate anywhere. C-9112.

GRADUATE ELECTRICAL ENGINEER, M. S. in E. E., 1931 from Massachusetts Institute of Technology majoring in communications.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
L. E. Griffith, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

Desires position with electrical company or as instructor in electrical engineering, physics or mathematics. Summer experience with telephone company. Available immediately. Location immaterial. Age 23. C-9674.

1931 TECHNICAL GRADUATE, B. Sc. in E. E. from a midwestern University, desires permanent connection with chance for advancement. Age 26. Location immaterial. Available immediately. C-9717.

ELECTRICAL ENGINEER, 1930, single, 22, graduate Pratt Institute. Desires position in any electrical line with opportunity for advancement. Has had electrical and mechanical engineering and drafting experience. Location immaterial. Available immediately. C-8380.

ELECTRICAL ENGINEER, 1924 graduate, B. S. E. E., 29, married. Seven years' experience testing, inspecting, installing various electrical equipment. Writing reports. Assistant to manager power and light utility. Purchasing electrical supplies. Available immediately. Detailed information, references gladly furnished. Welcomes opportunity particularly in operating, maintenance department, public utility or manufacturing concern. C-4981.

SALES EXECUTIVE. Not afraid to work, not too old to acquire new ideas. Electrical training, Worcester Polytechnic Institute. Seven years directing engineering sales and sales through distributors. Capable of contacting industrial or electrical field with either an electrical or mechanical product. Industrious, with dependent, ready to go to work. C-5481.

ELECTRICAL ENGINEER, 1928 graduate. Three years' experience in large industrial plant on maintenance and operation of all kinds of motors, switchboards, electric heating, pyrometers, regulators and transformers, both theoretical and practical. Desires any electrical position. C-9845.

TECHNICAL GRADUATE, 38, married; desires position in engineering or operating department of power company. Has had 11½ years' experience with distribution engineer and operating and construction departments of public utility; 1½ years test; and 3 years shop experience. Location immaterial. B-9248.

ELECTRICAL DESIGN ENGINEER, 25 years' experience with public utilities, industrial companies, steam, hydroelectric power plants, H. T. indoor and outdoor substations, copper and nitrate mining plants, layouts, specifications, purchase of equipment, able to take charge, seeks position of responsibility. New York State professional engineer's license. B-7031.

1931 GRADUATE, North Carolina State College, B. S. in E. E., 25. Would take position of any type that offers advancement. Member of Tau Beta Pi and Phi Kappa Phi. Willing to go anywhere. C-9865.

Membership

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before October 31, 1931.

Bennett, D. S., Worcester Electric Light Co., Worcester, Mass.

Bibish, J. E., Libbey Owens Ford Glass Co., Toledo, Ohio

Burch, W., Carolina Power & Light Co., Raleigh, N. C.

Craton, F. H., General Electric Co., Erie, Pa.

Davies, L. S., Provincial Mental Hospital, Essondale, B. C., Canada

Dubielzig, R. C., 3361 N. 24th St., Milwaukee, Wis.

Ellis, C. R. (Member) Electric Bond & Share Co., New York, N. Y.

Goodenough, F. J., Amalgamated Electric Corp., Toronto, Canada

Gove, H. E., Union Electric Light & Power Co., St. Louis, Mo.

Harrington, N. F., R. W. Cramer & Co., New York, N. Y.

Hart, J. W., Electric Bond & Share Co., New York, N. Y.

Hogan, J. P. (Member) Parsons, Klapp, Brinckerhoff & Douglas, Enggs. & Managers, New York City, N. Y.

Order Form for Pamphlet Copies of A. I. E. E. Papers*

Papers presented prior to September 1931 and upon which articles in this issue are based

Number	Author	Title
☐ 31-14	G. M. Schrum and H. G. Weist, Jr.	Some Experiments with Arcs Between Metal Electrodes
☐ 31-29	W. J. McClain	Electrical Distribution Systems for Industrial Plants
☐ 31-43	M. A. Hyde, Jr.	Synchronous Motor with Phase-Connected Damper Winding for High-Torque Loads
☐ 31-49	A. W. Hull and H. D. Brown	Mercury-Arc Rectifier Research
☐ 30-50	W. R. King	Electron Tubes in Industry
☐ 31-62	D. W. McLenegan and A. G. Ferriss	Synchronous Motors—Design and Application to Meet Special Requirements
☐ 31-70	E. V. DeBlieux	Losses in Transformers for Use with Mercury Arc Rectifiers
☐ 31-98	P. B. Juhnke	Communication Facilities of a Metropolitan Power System
☐ 31-104	R. N. Conwell, G. M. Keenan, C. F. Craig, and E. C. Briggs	Communication Serivces of Electric Utilities—Underlying Considerations
☐ 31-111	E. S. Bundy	Communication in the Western Division of the Niagara Hudson System
☐ 31-113	C. A. Booker and M. E. Clark	Cooperative Study of Power System Communication
☐ 31-116	E. C. Stewart	Communication on the Arkansas-Louisiana-Mississippi Interconnected System
☐ 31-132	J. Slepian and L. R. Ludwig	Backfires in Mercury Arc Rectifiers
☐ 31M8	P. N. Winther	Electric Arc Welding in Building Construction
☐ 31M13	O. H. Frier	Telegraphic Pilot-Wire Relay System

*Members, Enrolled Students, and subscribers are entitled to one pamphlet copy of any paper in this list if requested within one year from above date. Thereafter charge of twenty-five cents per copy will obtain.

New Books
In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during August are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following 'outlines, information for which is taken from the preface or text of the book in question.

BERECHNUNG VON DREHSTROM-KRAFTUBERTRAGUNGEN. By O. Burger. 2nd ed. Berlin, J. Springer, 1931. 183 pp., illus., diagrs., charts, tables, 8 x 6 in., cloth. 13.50 r. m.——A concise yet complete description of a practical method for the calculation of the electrical characteristics of three-phase transmission systems of any capacity. The method given is the outgrowth of many years of experience with the Siemens-Schuckert Works.

DIE BETRIEBSUNTERSUCHUNG WEGE UND FORMEN. By O. Bredt. Berlin, VDI Verlag, 1931. 56 pp., charts, tables, 12 x 8 in., paper, 12 r. m.——Dr. Bredt discusses the development of management-research in America and Europe and presents a detailed description of the methods used in five typical cases. These cases are then criticized in detail, and the efficacy of the methods used is discussed. The general principles and methods of procedure are then demonstrated by reference to an investigation by the National Board of Economics of Germany. The book shows the possibilities of management research and is a brief compendium of methods.

DIELECTRIC CONSTANT AND MOLECULAR STRUCTURE. American Chemical Society Monograph 55. By C. P. Smyth. N. Y., Chemical Catalog Co., 1931. 214 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.——The author has correlated and organized the known facts bearing upon the problems of electric moment, molecular structure and intermolecular action, and uses them in a critical examination of the theories and hypotheses in terms of which they are interpreted.

DRUCKWECHSEL UND STOSSE AN KOBLENMASCHINEN MIT SCHUBKURBELGETRIEBE. 1 v. Text and 1 v. Tables. By F. Kuba. Vienna, Julius Springer, 1931. 69 pp., diagrs., tables, 14 x 9 in., paper, 18 r. m.——A theoretical investigation of the phenomena accompanying reversals of pressure in reciprocating engines. The author develops a method of determining the relative velocity of the various phenomena, analyzes these phenomena into special components and points out the effect of changes in the conditions upon the relative magnitudes. The investigation aims to afford a sound basis for studying shocks in engine bearings, etc. A critical review of previous publications on the subject is included.

ECONOMICS FOR ENGINEERS. By E. L. Bowers and R. H. Rowntree. N. Y., McGraw-Hill Book Co., 1931. 490 pp., diagrs., charts, maps, tables, 9 x 6 in., cloth. $4.00.——This text-book on economics has been written to give engineering students a knowledge of economic principles and problems. The subject is presented very concisely, in order not to burden the curriculum unduly, and the engineering aspects of economic theory and business activity are emphasized. A practical presentation of the subject from an engineering point of view.

ENGINEERING PROBLEMS MANUAL. By F. C. Dana and E. H. Willmarth. 2nd edit. N. Y., McGraw-Hill Book Co., 1931. 252 pp., illus., diagrs., charts, tables, 8 x 5 in., $2.00.——This manual has been prepared primarily for use in the courses in engineering problems now given at some colleges to train the beginner in proper habits, effective methods and systematic workmanship, and to correlate his courses in physics and mathematics with engineering. It contains specifications for computation sheets, advice on habits of work and study, concise notes on fundamental principles and mathematics, three hundred practical problems and a collection of tables. The new edition has been revised and partly rewritten.

LE FACTEUR DE PUISSANCE, DES INSTALLATIONS ELECTRIQUES INDUSTRIELLES. By R Menjelou. Paris, Dunod, 1931. 239 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, 73 frs.——A systematic review of the power-factor problem. The effect of the power factor upon electric systems, the causes of a poor power factor and the methods by which it can be improved are discussed.

DAS FERNSPRECHWESEN III. SAMMLUNG GOSCHEN BD. 1043. By H. Schmidt. Berlin and Leipzig. Walter de Gruyter & Co., 1931. 139 pp., illus., diagrs., charts, 6 x 4 in., cloth, 1,80 r. m.——A brief elementary description of the principles of automatic telephony, describing the design and operation of the various types of apparatus in use.

FORSCHUNGSHEFT 346. WARMSPANNUNGEN IN GLEICHDRUCKWARMESPEICHERN. By E. Mayer. Berlin, VDI-Verlag, 1931. 23 pp., diagrs., charts, 12 x 9 in., paper, 5 r. m.——This research report deals with an experimental and theoretical investigation of the heat stresses in steam accumulators of the constant pressure type. The work was done at the Karlsruhe Technical University.

INHALTSVERZEICHNIS DER ZEITSCHRIFT DES VEREINES DEUTSCHER INGENIEURE, 1926-1930. Bd. 70-74, Berlin, VDI Verlag, 1931. 138 pp., 12 x 8 in., paper, 8 r. m.——This index, covering the last five volumes of the "Zeitschrift," contains over 3,500 entries to authors and subjects, and is an important guide to recent engineering developments, especially to the work of German engineers.

INTERNATIONAL CRITICAL TABLES OF NUMERICAL DATA, PHYSICS, CHEMISTRY AND TECHNOLOGY. INDEX v.1-7. By the National Research Council. N. Y., McGraw-Hill Book Co. 1930. 43 pp., 11 x 9 in., paper.——An index to the complete set, published in four languages, English, French, German and Italian.

MATERIALS OF CONSTRUCTION. By A. P. Mills. 4th ed., edited by H. W. Hayward. N. Y., John Wiley & Sons, 1931. 423 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.——The aim of this work is to supply a general text-book upon the manufacture, properties and uses of the common engineering materials, for students of engineering. The book is to be supplemented by a laboratory course in the testing of materials. The new edition has been revised and enlarged.

POWER AND THE INTERNAL COMBUSTION ENGINE. By W. E. Dalby. N. Y., Longmans, Green & Co., 1931. 280 pp., diagrs., charts, tables, 9 x 6 in., cloth, $7.00.——Professor Dalby here treats of the common principles of the internal combustion engine. The first chapter is devoted to the physical and thermodynamical properties of a working agent formed from a gaseous charge by explosion. The second chapter considers in more detail fuels and the charges formed by mixing them with air, and the products of their combustion. The engine and its performance are the subject of chapter four, which is followed by a chapter on the performance diagram devised by the author. Succeeding chapters are devoted to the suction gas plant, the gasoline engine, and the effect of heat flow on design. The book contains much to interest the designer.

PRINCIPLES AND PRACTICE OF GEOPHYSICAL PROSPECTING, report of the Imperial Geophysical Experimental Survey. Cambridge (England) University Press; N. Y., Macmillan Co., 1931. 372 pp., illus., diagrs., charts, maps, tables, 11 x 9 in., cloth, $5.00.——This report records the results of eighteen months of work in Australia, undertaken to test the applicability of the principal geophysical methods under field conditions, for the purpose of determining their practical value and relative merits. Electrical, gravimetric, magnetic and seismic methods were used in country carrying sulphide and other ores, graphite, brown coal, saline waters, etc. The report is more in the nature of a manual of geophysical prospecting, illustrated by field results, than of a formal report. In part one the field investigations and elementary expositions of the different methods are given in readily understood form. Part two explains the field procedure in greater detail and discusses the design of apparatus, the interpretation of results and the underlying theory. Much new information upon electrical instruments is included.

SCIENCE AND RELIGION, a Symposium with a foreword by M. Pupin. N. Y., Charles Scribner's Sons, 1931. 175 pp., 8 x 5 in., cloth, $1.75.——In the fall of 1930 the British Broadcasting Corporation arranged a series of talks, in which eminent scientists, churchmen, and philosophers were asked to give their personal interpretation of the relation of science to religion and to determine to what degree the conclusions of modern science affect religious dogma and the fundamental tenets of Christian belief. These addresses now appear in print. with a oreword by Professor Pupin, and are, of unusual interest as a representation of the mature thought of distinguished leaders in the two fields. Among the twelve contributors are Sir J. Arthur Thomson, Julian Huxley, Sir Arthur Eddington, the Bishop of Birmingham, Dean Inge and Canon Streeter.

TELEVISION. By E. H. Felix. N. Y., McGraw-Hill Book Co., 1931. 272 pp., illus., diagrs., charts, 8 x 5 in., cloth, $2.50.——This book explains the basic processes involved in any television system and describes the methods of existing systems. The standards of performance requisite to commercial service are outlined, and the limitations of existing methods are pointed out. The book gives a good general survey, in not too technical language, of the present situation, the problems that television faces, and its probable future.

VECTOR REPRESENTATION FOR ELECTRICAL METERMEN. By D. T. Canfield. N. Y., McGraw-Hill Book Co., 1931. 180 pp., diagrs., charts, tables, 8 x 6 in., cloth, $2.00.——This book explains the vector representation of alternating voltages and currents in simple language, with very little use of mathematics. The theory of vectors and their manipulation are first described in a non-mathematical, non-technical way. This is followed by a more technical presentation of the subject, after which the use of vectors in the solution of polyphase problems and power-factor correction is shown by practical examples. While intended primarily for metermen, the book will be useful to any one seeking an elementary text.

2ND WORLD POWER CONFERENCE, Berlin, 1930. Transactions, Bd. 20, Index. Berlin, VDI-Verlag, 10 x 6 in., cloth, $85.00 per set.——This volume completes the Transactions of this conference, held in Berlin in June, 1930. The Transactions contain the papers presented, numbering over three hundred and fifty. These are in twenty volumes of handy size, each containing papers upon related subjects, which may be purchased singly. These are fully indexed by author and subject in this final volume. The index is tri-lingual—English, German, and French.

FRENCH-ENGLISH AND ENGLISH-FRENCH DICTIONARY OF COMMERCIAL AND FINANCIAL TERMS, PHRASES AND PRACTICE. By J. O. Kettridge. N. Y., E. P. Dutton & Co., 1931. 647 pp., 10 x 7 in., cloth, $7.50.——This work gives the translations of fifty thousand words, terms and phrases frequently used in commercial and financial writings, and illustrates their use by numerous examples and explanations. The book is clearly printed and of convenient size. It will fill a long felt want among translators, as it occupies a new field, and will do so very satisfactorily.

CREEP OF METALS. By H. J. Tapsell. London, Oxford University Press, 1931. 285 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, 30 s. (American Price $12.00).——A very complete presentation of the data available upon the creep of metals at high temperatures. The work of the various investigators has been correlated, in the light of the test methods used by them, with the aim of enabling the engineer to a satisfactory interpretation of present and future data, and the successful use of them.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Selected Items From
Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Armatures

WINDINGS. Unbalanced Voltage in Armature Coils, R. M. Baker. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 315-317, and 321, 12 figs. Set-up for studying circulating current conditions by means of oscillograph analysis of results.

Busbars

Current-carrying Capacity of Bare Cylindrical Conductors for Indoor and Outdoor Service, C. W. Frick. *Gen. Elec. Rev.*, vol. 34, no. 8, Aug. 1931, pp. 464-471, 8 figs. Carrying capacity tables for bare indoor conductors and at 100 per cent conductivity copper, horizontal position, 40 deg. cent. air temperature in large rooms without drafts and 60 cycles and for bare outdoor conductors of same material in partly sheltered locations; relative capacities for conductors of same diameter and cross-section made of metals having different values of conductivity; formulas for calculation of current *vs.* temperature rise; resistance data.

TESTING. Aluminum Busbars Resist Power Arcs, J. D. Porter. *Elec. World*, vol. 98, no. 3, July 18, 1931, pp. 104-105, 1 fig. Tests made by engineers of Westinghouse Electric & Manufacturing Co.'s high-power laboratory on behalf of Aluminum Co. of America, in order to determine effect of power arcs of long duration on tubular aluminum busbar under various currents and with several different weights and thicknesses of tubing.

Cables

DIELECTRIC LOSSES. The Significance of Dielectric Loss in High Voltage Cables, M. C. Timms. *Elec. Engr. Australia and New Zealand*, vol. 8, no. 3, June 15, 1931, pp. 95-100, 5 figs. Origin of dielectric loss; leakance; ionization loss; analysis of dielectric loss; effect of inherent dielectric loss; variation of power factor; effect of ionization loss.

Dielectric Loss-Angle Measurement of Multi-Core High-Tension Cables, With Special Reference to the Schering Bridge, L. G. Brazier. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 414, June 1931, pp. 757-770, 14 figs. Special difficulties of dielectric loss angle; measurement on multi-core cables are examined; conclusion is reached that inter-admittance cannot be considered to have associated with it definite dielectric loss-angle; new method of obtaining inter-dielectric loss-angle in conformity with conclusions of section; wavelength effect appreciably affects apparent dielectric loss-angle when cable exceeds in length small fraction of wavelength.

Cables, Telephone

FAULT LOCATION. Bridge Methods for Locating Resistance Faults on Cable Wires, T. C. Henneberger and P. G. Edwards. *Bell System Tech. Jl.*, vol. 10, no. 3, July 1931, pp. 383-407, 18 figs. Bridge methods for locating resistance faults on cable wires, with special reference to theory of methods for locating insulation faults which cause complete cable failure, locating insulation faults of high resistance, and locating series resistance unbalances.

NOISE ELIMINATION. Telephone Cable Circuit Noise and Power Distribution Systems. *Nat. Elec. Light Assn.—Pub.*, no. 147, July 1931, 4 pp., 5 figs. Results of study made to determine factors involved in power distribution systems and telephone exchange plants which contribute to noise problem; relative influence of various types of power distribution systems and relative susceptiveness of various types of telephone exchange cable circuits are shown.

Circuit Breakers

How Deion and Deion-Grid Circuit Breakers Operate, H. N. Blackmon. *Power*, vol. 74, no. 5, Aug. 4, 1931, pp. 161-163, 8 figs. Two high-voltage circuit breakers, Deion, which is air-break type and Deion-grid, oil-break type, have come into use recently; although both remove ions from arc when interrupting circuit, they operate on entirely different principles.

Clocks, Electric

MOTORS. Measuring 0.000011 Horsepower, T. R. Watts. *Elec. Jl.*, vol. 28, no. 7, July 1931, p. 418, 3 figs. Special spring dynamometer was recently constructed for running speed-torque tests on 200 r. p. m. clock motors of approximately 11 millionths of hp.

Diesel Electric Plants

AUTOMATIC. Automatic Diesel-Electric Plant, E. J. Kates. *Machy. Market*, no. 1604, July 31, 1931, pp. 19-20. Paper before Am. Soc. Mech. Engrs., previously indexed from Advance Paper, for mtg. June 23-26.

Dust Precipitation

ELECTRIC. Harvard Medical Power Extension Precipitates Dust Electrically, G. K. Sauerwein. *Power*, vol. 74, no. 7, Aug. 18, 1931, pp. 226-229, 6 figs. Variety of services applied by Harvard Medical School power plant, which employs electrostatic precipitation of flue dust; design and operating characteristics of boiler plant equipment.

Education

Education for the Engineering Industry, Lond., H. M. Stationery Office, 1931, 67 pp., 1s. 3d. Report of Committee on Education for Engineering Industry and comments on report by educational bodies; factors in recruitment to industry; recruitment from different types of school and from Universities; training in works; promotion in relation to training and instruction; organization of part-time education; subjects of instruction in technical schools and colleges; trade courses; foundry work; instruction in crafts; conclusion.

Electric Drive

Individual or Group, D. C. McGuire. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, pp. 456-459, 2 figs. For average installation, when all factors have been considered, first cost for individual motor drive and for group drive is approximately same; power and labor costs are more important than first cost; overall efficiency of drive should be accurately determined because cost of power is largest single item entering into cost of operation; various tables showing installation operation costs are given.

New Multi-Speed Drive. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, p. 490, 2 figs. Movement of handle selects any one of four speeds for driven equipment, constant-speed motor running under full load; drive has motors and gears made in single unit, and is designed for constant horsepower output.

CALENDARS. Synchronizing Operation of Calendar Trains, R. G. Lockett. *Chem. and Met. Eng.*, vol. 38, no. 7, July 1931, pp. 407-409, 3 figs. Control problem centers around necessity of handling group of motors in unison at various speeds and at times arranging for adjustable "draw" between units; rubber-tire fabric calendars ordinarily are driven by two to one d-c. motors operating on two-voltage system, while some forms of textile-printing machines operate on variable-voltage d-c. system providing much greater speed variation.

STEAM POWER PLANTS. Large and Small Motors in the Modern Industrial Steam Power Plant, E. A. Murray. *Eng. and Finance*, vol. 25, no. 1, July 1931, pp. 7-8. General types of electric motors for essential and non-essential auxiliaries in power plant; mechanical construction and control.

Electric Equipment

COAL MINES. Automatic Portable Conversion Equipment at the Wildwood Mine of the Butler Consolidated Coal Co., A. L. Lee. *Gen. Elec. Rev.*, vol. 34, no. 8, Aug. 1931, pp. 459-463, 6 figs. Portable starting and running equipment for portable motor-generator set of 300 kw., 2,300 volts a-c., 275 volts d-c., 1,200 r. p. m.; details of substation.

Electrolytes

The Rapid Determination of Current Efficiency in the Electrolysis of a Zinc Sulfate Electrolyte. *Electrochem. Soc.—Preprint*, no. 60-1, for mtg. Sept. 2-5, 1931, 7 pp., 2 figs. Roasted blende is leached with spent acid sulphate from cell room; before discharging zinc-enriched solution back into cells, it is advisable to test it as to cathode efficiency, which is sensitive indicator of quality of solution; new apparatus and comparatively described have been in satisfactory use for several months.

Engineers

RUSSIA. American Engineers in Russia, J. M. Carmody. *Eng. News-Rec.*, vol. 107, no. 7, Aug. 13, 1931, pp. 262-264. Comments upon engineering status, living conditions, technical problems and future prospects; employment contracts; engineers must be teachers.

Frequency Meters

VACUUM TUBE. A Thermionic Type Frequency Meter For Use Up to 15 KC, F. T. McNamara. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1384-1390, 7 figs. New type of frequency meter which is adapted to measurement of low and intermediate frequencies; instrument absorbs negligible amount of power from circuit being tested, has linear calibration curve and sensitivity of about eight microamperes for one per cent change in frequency; experimental model is described in detail; input is between five and ten volts; other models may require different inputs.

FURNACES. Welding Stresses are Relieved in the Electric Furnace, C. C. Brinton. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, pp. 478-479, 5 figs. Car-type furnace for use in reducing welding stresses; floor and front wall are mounted on truck that moves in and out of furnace proper; three heater banks are connected star-delta from 60-cycle, 2,300-volt supply source through three 2,300-230/115-volt transformers, with circuits so arranged that each bank may be operated independently; furnace rating is 375 kw., 60 cycle, three phase.

COOLING. Electrical Furnaces with Artificial Atmospheres. *Nat. Elec. Light Assn.—Pub.*, no. 141, July 1931, 9 pp., 16 figs. Value of artificial atmospheres, processes and furnaces which lend themselves to use of artificial atmospheres; gases used and their source of supply; possible future applications; specific uses of artificial atmospheres and functions of gases; illustrations showing furnaces, objects and charges treated, and gas generating equipments.

Fuses

Fuse Performance in Circuit-Interrupting Service, H. D. Braley. *Power*, vol. 74, no. 4, July 28, 1931, pp. 130-133, 11 figs. Fuse considered in its ability to interrupt circuit, and factors that influence its performance in that duty; results of series of overload tests made on different size fuses.

Generators

CONTROL. Automatic Direct-Current Load Shifting Control, L. D. Whitelock. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 289-290, 2 figs. Load-shifting apparatus controls d-c. generator voltage instead of placing resistors in bus system; its cost is so reasonable that it is now feasible to install automatic load-shifting equipment in stations which would otherwise be manually operated.

Hydroelectric

POWER DEVELOPMENTS. Hydroelectric Development of the Mokelumne Basin, E. A. Crellin. *Elec. West*, vol. 67, no. 2, Aug. 1, 1931, pp. 54-62, 18 figs. Highest of its kind, Salt Springs rockfill dam halts Mokelumne River, impounding water to produce now 71,000 kva., eventually to supply white coal to four plants with 176,000 kva. installed capacity; descriptions of Salt Springs power house, Tiger Creek conduit, and Tiger Creek power house; wiring diagrams are given.

POWER PLANTS. Saluda Development is Rich in New Engineering Features, A. P. Campbell, J. P. Garvin, A. W. Reed, and N. D. Urquhart. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 265-268, 7 figs. Plant has added additional 130,000 kw. to generating capacity in South Carolina, besides having created second largest artificial lake in United States, and largest earth filled power dam in world; built for Lexington Waterpower Co. on Saluda River near Columbia, S. C., it will have ultimate capacity of 195,000 kw., at present four 32,500 kw. generators are installed.

Maintaining Equipment in Hydroelectric Plants, J. E. Housley. *Power*, vol. 74, no. 7, Aug. 18, 1931, pp. 239-241, 4 figs. Inspection and maintenance methods that have proved successful and are outgrowth of eleven years' experience on system that has increased in size to where there is now nearly 300,000 hp. installed capacity.

REMOTE CONTROL. Remote-Controlled Hydro Station. *Elec. World*, vol. 98, no. 4, July 25, 1931, p. 154, 1 fig. Remote automatic controls for hydro stations are used very frequently; diagram showing essential features of remote-control system developed and applied by General Control Corp.; operation.

WATER STORAGE. Chart Simplifies Water-Flow Problems, R. Ball. *Power*, vol. 74, no. 6, Aug. 11, 1931, pp. 202-203, 2 figs. By use of storage-reservoir-capacity curve and second-foot scale, problems on available water for power generation are easily worked out.

Lamps

ULTRAVIOLET. A New Source of Ultraviolet Radiation, J. W. Marden and M. G. Nicholson. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 6, July 1931, pp. 592-601 and (discussion) 601-610, 8 figs. partly on supp. plate. Type of mercury vapor ultraviolet lamp, with possibilities; discussion on mechanical construction, electrical characteristics, and development problems encountered; curves, oscillograms and drawings are included; problem of measuring ultraviolet output; brief treatment of ballast devices to be used with lamp is given, and method of adapting these and glow lamp on 115-volt circuit is considered.

Lighting

Physical Characteristics of Sunshine and Its Substitutes, C. E. Greider and A. C. Downes. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 6, July 1931, pp. 561-571, 6 figs. partly on supp. plates. Measurements made of energy distribution of solar radiation throughout spectrum and of its variation with altitude, location and time of year; attempt has been made to correlate these physical data with clinical experience as to best kind of sunlight for health maintenance; biological significance of various portions of sun's spectrum is discussed; comparison between natural sunlight and one type of artificial sunlight. Bibliography.

The Biologically Active Component of Ultraviolet in Sunlight and Daylight, W. W. Coblentz. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 6, July 1931, pp. 572-577. Attention is called to atmospheric pollution by products of combustion of automobiles and oil-burning heaters, which greatly reduce intensity of ultraviolet vitalizing rays of sunlight; biological data are cited showing that, while healing of rickets is possible in strong light from sky, for effective therapeutic results, obtainable by exposure for convenient interval of time, direct exposure to sunlight is essential. Bibliography.

VISION RELATIONSHIP. Seeing, a Partnership of Lighting and Vision, M. Luckiesh and F. K. Moss. Baltimore, Williams and Wilkins Co., 1931, 241 pp., illus., diagrs., charts, $5.00. Seeing depends upon light and lighting, as well as upon eyes and visual sense; yet light and lighting have not yet received much consideration as partner of visual sense, although excellent scientific data pertaining to vision are available; present book aims to remedy this lack, in part, by giving results of extensive research work, covering some twenty years and undertaken to establish scientific principles of seeing. Bibliography. Eng. Soc. Lib., N. Y.

AIRWAY. Requirements for Airdrome and Air-Route Lighting at Present Time, C. E. Ward and W. M. Hampton. *Cinquieme Congres International de la Navigation Aérienne (5th International Congress of Aviation)*, vol. 1, Sept. 1-6, 1930, pp. 192-199. Requirements from viewpoint of pilots and navigators; limits imposed on lighting installation by costs, standardization of apparatus to simplify manufacture, installation and maintenance; responsibility for installation as it concerns governments, municipalities and aircraft operating companies; difference between needs of commercial aircraft operators and private owners of aircraft or amateur pilots. (In English.)

MEASUREMENT. The Photoelectric Measurement and Photographic Recording of Daylight, W. A. Thomson. *Can. Jl. Research*, vol. 4, no. 6, June 1931, pp. 559-564, 7 figs. Method is described by which illumination intensities were measured by photoelectric cell and galvanometer, and continuous photographic record obtained of variations of intensity over period of time during which ground was covered with snow; it was found that remarkable increase in illumination was caused by presence of cloudiness with full sunshine.

ULTRAVIOLET. The Mercury Arc in Hygienic Illumination, L. J. Buttolph. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 6, July 1931, pp. 578-591, and (discussion) 601-610, 14 figs. To meet general conviction that there must be perceptible erythema as evidence of beneficial effect from ultraviolet in hygienic industrial illumination, Cooper Hewitt lamp will be constructed of glass having increased ultraviolet transmission; value of new lamp is predicted graphically from its relative energy distribution, and erythematic effect curves.

Lines

CALCULATION. Line Loss Calculations, S. W. Marshall, Jr. *Gen. Elec. Rev.*, vol. 34, no. 8, Aug. 1931, pp. 472-473, 1 fig. Theoretical, mathematical analysis; calculations are based on assumption of constant value of charging current per mile for transmission line, constant value of transformer exciting current and constant iron loss for load terminal transformers.

DESIGN. Sags and Tensions in Overhead Lines, C. G. Watson. London and New York, Isaac Pitman and Sons, 1931, 192 pp., diagrs., charts, tables, $3.75. Simple methods of determining sags and tensions which are accurate, yet require no further mathematical knowledge than ability to plot and read graphs, and perform simple arithmetical operations; tables and graphs of hyperbolic and catenarian functions of tangents, etc. Eng. Soc. Lib., N. Y.

LIGHTNING PROTECTION. Direct Strokes to Transmission Lines, W. W. Lewis and C. M. Foust. *Gen. Elec. Rev.*, vol. 34, no. 8, Aug. 1931, pp. 452-458, 8 figs. Potential gradients preceding nearby lightning strokes; cloud field gradients during lightning storm; polarity characteristics of breakdown; Lichtenberg figures; protection afforded by lightning rods; variation of Lichtenberg figure streamer length with applied voltage; characteristics of lightning strokes; field records of direct strokes to transmission lines; direct strokes on transmission lines and tripouts; conclusions of analysis.

PROTECTION. Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 299-305, 13 figs. Line-fault protection of loop systems analysis pertaining to fault calculations; application of relays; setting of impedance relays.

RELAYS. Theory and Application of Relay Systems—Gound-Fault Protection of Loop Systems—II, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 7, July 1931, pp. 431-435, 16 figs. Ground-fault currents; application of relays; calculation of ground-fault currents.

Theory and Application of Relay Systems—High-Voltage, Single-Circuit Lines, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, pp. 485-488, 11 figs. Overcurrent relays; directional-overcurrent relays; directional residual ground relay; polyphase directional-overcurrent relay; fault-detector relay schemes; impedance relay; bus protection; pilot wire relaying; various wiring diagrams are given.

VIBRATIONS. Safeguarding from Vibration, E. C. Thompson. *Elec. Light and Power*, vol. 9, no. 8, Aug. 1931, p. 34, 1 fig. Layout gives idea of work done in installing vibrations dampeners on Jordan Dam-Flomaton line of Alabama Power Co.

Loud Speakers

MEASUREMENT. Notes on Loud Speaker Response Measurements and Some Typical Response Curves, B. Olney. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 7, July 1931, pp. 1113-1130, 10 figs. Difficulties in loud speaker measurements; acoustic features of particular indoor measuring system; outdoor testing arrangements whereby double as well as single radiating loud speakers are measured with negligible ground reflection error; over-all electrical fidelity curve of radio receiver is inadequate performance index; electro-acoustic fidelity embracing frequency response of loud speaker is suggested as more informative.

Machinery

TESTING. Short-Duration Temperature Testing of Electrical Machines, W. E. French. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 415, July 1931, pp. 867-874, 9 figs. Method for rapid determination of temperature-rise and time-constant of electrical machinery and apparatus, based on exponential heating and Hak curves, tests are produced showing that there is satisfactory agreement between figures and curves of graphical method by short-duration tests and those obtained by measurement from long heat-runs; theory of Hak curve.

Motors

SPEED REGULATION. Motor Applications for Drives Requiring Speed Changes, E. C. Dieffenbach. *Power*, vol. 74, no. 3, July 21, 1931, pp. 80-83, 7 figs. Because of nature of work speed adjustments are essential in multitude of motor drives, ultimate object being to save power and to speed up production; speed variations with motors may be obtained in many ways, 15 methods being discussed.

Musical Instruments

Electronic Musical Instruments, R. Raven-Hart. *Electronics*, vol. 3, no. 1, July 1931, pp. 18-19, and 42, 1 fig. Holding of international congress on subject of electronic music by European inventors and manufacturers of electronic musical devices shows practical extent to which new musical devices have already progressed in Germany, France and other European countries.

Networks

ANALYZERS. Phase Faults Analyzed on D-C. Calculating Board, C. W. Bohner and G. W. Vaughan. *Elec. World*, vol. 97, no. 23, June 6, 1931, pp. 1068-1071, 4 figs. Single-phase-to-ground shorts create unsymmetrical fault currents in phases; paper exhibits technique in ascertaining from direct-current calculating board zero-positive and negative phase sequence components of dissymmetry.

INVERSION. Inversion of System Resulting from Switching Operations, A. Boyajian and W. J. Rudge. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 436-439, 18 figs. Equivalent impedance network of system may be altogether different in character from normal, during various stages of switching operations; usually these are of no particular consequence, but occasionally destructive conditions are encountered; simplest single-phase circuits susceptible of such phenomena are taken as basis for general exploration of phenomena and are applied to three-phase system.

PROTECTION. Installation Protection, T. C. Gilbert. *Elec. Rev.*, vol. 109, no. 2799, July 17, 1931, pp. 93-94, 3 figs. Rheinisch-Westfalisches Elektrizitatswerk has solved problem of usual protective methods in rural conditions by installation of extremely interesting protective devices, both at substations and also on consumer's premises.

TESTING. Automatic Recording of System Disturbances, J. T. Johnson, Jr. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, pp. 466-468, 6 figs. Multi-element oscillograph gives complete record of currents and voltages during transient, starting from rest within four cycles.

Oscilloscopes

A New Cathode-Ray Oscilloscope, W. O. Osborn. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 322-324, 6 figs. Distinctly new type of oscillograph has been developed; with it recurring phenomena, such as wave shapes of voltage or current can be viewed on a fluorescent screen in ordinarily lighted room; yet complete oscilloscope is contained in cabinet about size of suitcase and is readily portable.

Photoelectric Cell

CONTROL. Photoelectric Relays and Monorail System Speed Mail Handling, H. L. Bohm. *Steel*, vol. 89, no. 5, July 30, 1931, pp. 31-33, 4 figs. Photoelectric tube control for monorail conveyor system designed to handle mail bags in railroad terminal.

MOVING PICTURES. Phototube Circuit Design for Sound-Pictures, C. A. Wyeth. *Electronics*, vol. 3, no. 1, July 1931, pp. 22-23 and 44, 5 figs. In selecting most suitable type of phototube to be used in reproduction of sound from film, many factors, both electrical and mechanical, must be considered; chief among electrical factors are frequency response characteristic, sensitivity, impedance and noise level and mechanical factors are shape and siz of cell, mounting facilities required, and sturdiness of physical construction.

Power Factor

IMPROVEMENT. Power Factor Improvement, J. Sachs. *AEG Progress*, vol. 7, no. 7, July 1931, pp. 139-145, 17 figs. Relation between active and reactive power; reason for power factor improvement and question as to where and by which means power factor should be improved is considered; design and service characteristics of static condensers; brief review of rotary condensers; various methods of improving power factor of induction motors by three-phase exciters, etc., and synchronous induction motor.

Power Factor Correction by Means of Permittors, A. A. Bolsterli. *Ry. Elec. Engr.*, vol. 22, no. 7, July 1931, pp. 178-180, 3 figs. Physical and economic factors involved in use of static condensers for improving power factor; description of 100-kva., 4,000-volt, 60-cycle permittor; 50-kva., 11,000-volt, 25-cycle permittor used for traction systems.

Poles

WOODEN. Life of Butt-Treated Western Red Cedar Poles, R. M. Wirka. *Elec. World*, vol. 98, no. 6, Aug. 8, 1931, pp. 237-239, 4 figs. Long-time test now under way in vicinity of Los Angeles, Calif., indicates that Western red cedar poles well butt treated with creosote by hot-and-cold-bath process will under such service conditions give average life of at least 25 years; where longer life than 25 years is required under similar conditions top treatment seems necessary; specification of preservatives; table showing condition of experimental Western red cedar poles in and around Los Angeles, Calif., after about 21 to 32 years' service.

STANDARDIZATION. New Standard Specifications for Wood Poles, R. L. Jones. *Bell System Tech. Jl.*, vol. 10, no. 3, July 1931, pp. 514-524, 2 figs. Work of Sectional Committee on Wood Poles of American Standards Assn. covering preparation of specifications for northern white cedar, western red cedar, chestnut and southern pine poles is summarized; major problems underlying development of standard ultimate fiber stresses, standard dimension tables and practical knot limitations are discussed and illustrated by supporting tables or figures.

Power Supply

RURAL. Electricity and the Agriculture of the Next Ten Years, E. A. White. *Agric. Eng.*, vol. 12, no. 8, Aug. 1931, pp. 301-305, 4 figs. Present trend in agriculture and predicted influence of electricity during next ten years. Before Am. Soc. Agric. Engrs.

Radio Antennas

MODULATION. Relations Between Modulation and Antenna Current, W. F. Lanternman. *Electronics*, vol. 3, no. 2, Aug. 1931, p. 59, 1 fig. Mathematical analysis pertaining to increase in antenna current due to power in sidebands; tables show increase in antenna current in relation to per cent of modulation.

SHORT WAVE. Developments in Short-Wave Directive Antennas, E. Bruce. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1406-1433, 23 figs. Relative importance of factors which limit intelligibility of short-wave radio telephone communication; more important of these factors are inherent set noise, external noise (static, etc.), and signal fading; possibility of counteracting these limitations through antenna directivity is indicated; antenna system which maintains desirable degree of directivity throughout broad continuous range of frequencies is described.

The Determination of Power in the Antenna at High Frequencies, A. H. Taylor and H. F. Hastings. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1870-1883, 9 figs. Brief review of general methods of measuring radio-frequency power in antenna; series of tests on particular transmitter operating from 4,000 to 26,000 kc.; tests indicate that it is reasonable for such transmitter continuously variable in frequency and of fairly modern design to be expected to put not less than 50 per cent of its input plate power of last stage into antenna as radio frequency from 4,000 kc. to 8,000 kc. and not less than 82 per cent at 24,000 kv.

Radio Engineering

Experimental Radio Engineering, J. H. Morecroft. N. Y., John Wiley and Sons, 1931, 345 pp., illus., diagrs., charts, tables. $3.50. Laboratory course in principles of radio; 51 experiments are given, designed to bring out characteristics of component parts of receiving and transmitting apparatus, and there is an introduction upon laboratory apparatus. Eng. Soc. Lib., N. Y.

Foundations of Radio, R. L. Duncan. N. Y., John Wiley and Sons, Inc., 1931, 246 pp., illus., diagrs., tables. $2.50. An introductory textbook on electricity, covering in non-mathematical language fundamentals of interest to student of radio engineering. Eng. Soc. Lib., N. Y.

Radio Frequency

MEASUREMENT. Measuring the Frequencies of Radio Signals, A. A. Roetken. *Bell Laboratories Rec.*, vol. 9, no. 12, Aug. 1931, pp. 585-588, 2 figs. By beating incoming radio signal down in successive known steps, its frequency can be accurately determined with audio-frequency oscillator; equipment at Holmdel is illustrated and described.

Radio Receivers

CRYSTAL CONTROLLED. Application of Piezo-Electrical Crystals to Receivers, R. R. Batcher. *Electronics*, vol. 3, no. 2, Aug. 1931, pp. 57-58, 4 figs. Analysis of quartz crystal bridge circuit in intermediate frequency amplifier of super-heterodyne receiver and development of simple relation between degree of unbalance and impedance of quartz crystal and holder which governs response of bridge as whole; it is shown that almost all of one sideband is eliminated but that other gets through to transmit desired modulation.

Radio Waves

ATTENUATION. Investigation of the Attenuation of Electromagnetic Waves and the Distances Reached by Radio Stations in the Wave Band from 200 to 2,000 Meters, H. Fassbender, F. Eisner and G. Kurlbaum. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1446-1470, 25 figs. Results of large number of field strength measurements in which relative radiation characteristics of transmitting and receiving stations remain constant even on changing their distance; constant of attenuation as function of wavelength was determined for propagation of waves over land from these measurements; method used eliminates errors in absolute determination of received field strength.

PROPAGATION. Radio Transmission Studies of the Upper Atmosphere, J. P. Schafer and W. M. Goodall. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1434-1445, 9 figs. Number of measurements which show time variations in virtual height of ionized regions of upper atmosphere; these measurements were usually made simultaneously on two frequencies, 1,604 kc. and 3,088 kc.; single frequency data are also given; main points of interest are presented.

Railroad

SIGNALS AND SIGNALING. Positive Control by the new Quebec Tunnel Signal System, E. S. Taylor. *Elec. News*, vol. 40, no. 15, Aug. 1, 1931, pp. 39-40, 4 figs. Mile-long tunnel has just been completed by Canadian Pacific Railway as direct link between its main line and new round-house for its great White Empresses, at Wolfe's Cove, Quebec; one of interesting features of this new project is unique and modern signal system for safety and guidance of trains into and out of Quebec, and also for those which use tunnel; system is briefly described.

Indianapolis Union Station Installs Electro-Pneumatic Interlocking. *Ry. Signaling*, vol. 24, no. 8, Aug. 1931, pp. 265-268, 6 figs. Nearly 200 train movements each day are now made with greater safety and flexibility; features of interlocking machine, signals, field apparatus, power supply and air supply.

Centralized Traffic Control Installed on Wabash. *Ry. Signaling*, vol. 24, no. 7, July 1931, pp. 231-236, 7 figs. Outstanding features of centralized control traffic installation on 37 mi. of single track line on Wabash railway between LaFayette Junction, Ind., and State Line; track layout and traffic; dispatcher's machine 93 mi. from distant end of 37 mi. single-track installation; operating savings justify cost; special signal requirements; power supply system.

New Interlocking on the Toronto, Hamilton and Buffalo at Hamilton, Ont. *Ry. Signaling*, vol. 24, no. 7, July 1931, p. 245, 5 figs. Old layout replaced by 72-lever plant; new cable distribution constructed under traffic without stopping train; interlocking machine and tower.

New Interlocking for the St. Louis Municipal Bridge. *Ry. Signaling*, vol. 24, no. 8, Aug. 1931, pp. 280-282, 5 figs. Simplicity of circuit arrangement and unique tower are features of 64-lever electric plant; battery and power room; relay room.

Interlocking. *Am. Ry. Signaling Principles and Practices*, Chapter 16, 1931, 65 pp., 43 figs. Definitions; types; historical review; application; track layout; layout and operating features of inside apparatus; 361 questions dealing with interlocking.

SUBSTATIONS. Habitant Style Disguises City of Montreal's Latest Automatic Railway Substation. *Elec. News*, vol. 40, no. 15, Aug. 1, 1931, pp. 31-32, 4 figs. Fourth mercury-arc rectifier substation installed by Montreal Tramways Co. contains two 1,500-kw., 12-phase, 600-volt units; station and equipment are described.

Rate Making

POWER INDUSTRY. A Composite Block Tariff, L. G. Hill. *Elec. Rev.*, vol. 109, no. 2798, July 10, 1931, p. 47, 3 figs. Lack of suitable standard tariff is probably greatest obstacle to domestic electrical development; what engineer has to pay for his bulk supply and how best these charges can be applied to domestic consumers; teaching the consumer to think in terms of hundreds of kilowatt-hours.

Reactors

CURRENT LIMITING. Development of Large Current-Limiting Reactors, R. B. George. *Elec. Jl.*, vol. 28, no. 8, Aug. 1931, pp. 460-463, 10 figs. Design development and testing procedure of dry-tube and oil-immersed current-limiting reactors; increased reactor sizes.

Rectifiers

MERCURY ARC. Mercury-Arc Rectifiers, W. E. Gutzwiller. *Power*, vol. 74, no. 2, July 14, 1931, pp. 44-47, 6 figs. Analysis of rectifier performance compared with that of synchronous converters and motor-generator sets.

VOLTAGE REGULATION. Voltage Regulation in Rectifier Plants, N. Kotschuboy. *Brown Boveri Rev.*, vol. 18, no. 7, July 1931, pp. 223-233, 22 figs. By production of new tapping switches permitting number of steps to be increased up to 60, it was possible to limit use of induction regulators to infrequent cases; automatic control of such tapping switches greatly simplifies operation of rectifier plants, thus enabling important savings to be made.

Registration

Important Changes Proposed in Uniform Registration Law, T. K. Legare. *Eng. News-Rec.*, vol. 107, no. 7, Aug. 13, 1931, pp. 266-267. President, National Council of State Boards of Engineering Examiners, recommends definite educational qualifications for professional engineers and land surveyors; satisfactory definition of engineering sought.

Steam Electric Plants

HIGH PRESSURE. Station "A" Initiates Use of High-Pressure Steam in the West, W. G. McKay and O. E. Steinbeck. *Elec. West*, vol. 67, no. 2, Aug. 1, 1931, pp. 68-71, 3 figs. Boiler pressures of 1,400 lb. are used in new steam station of Pacific Gas and Electric Co. in San Francisco; 100,000 kva. is generated by two turbine-generator sets recently installed to supply increased energy requirements of Bay area.

Steel Corrosion

UNDERGROUND. The Electrolytic Corrosion of Underground Metallic Structures by Stray Currents, O. M. Longfield. *Instn. Engrs. Australia—Jl.*, vol. 3, no. 5, May 1931, pp. 157-168, 21 figs. Nature of electrolysis of subsurface structures and conditions bringing it about; discussion of field surveys, results obtained, and to what extent observed phenomena can be used as estimation of damage; remarks about instruments for use in field, and in particular of slow speed oscillograph adapted by author; mitigative measures are critically discussed; importance of protective coatings for steel mains is stressed.

Substations

AUTOMATIC. 10 Years' Experience with Automatic and Supervisory Distribution Substations, F. F. Ambuhl. *Elec. News*, vol. 40, no. 15, Aug. 1, 1931, pp. 35-37 and 51, 5 figs. Toronto Hydroelectric System has long realized advantages and economies of automatic and supervisory control; as result, all new stations built since 1920 have been designed for either automatic or supervisory control; automatic controls have given fairly satisfactory results and supervisory controls have given excellent results, especially cable type supervisory. Before Am. Inst. Elec. Engrs.

REMOTE CONTROL. Synchronism Checked by Voltmeter, F. M. Lewis. *Elec. World*, vol. 97, no. 23, June 6, 1931, p. 1056, 1 fig. Northwestern Electric Co. completed substation in business district of Portland which will be remotely controlled until station becomes large enough to require an operator; to save expense of installing additional control wires; synchroscopes; synchronizing switches or synchro-verifier relays; special voltmeter connection for checking synchronism between line and bus was made.

Visicode Supervisory Control, L. J. Cissna. *Elec. Jl.*, vol. 28, no. 7, July 1931, pp. 424-425, 3 figs. Visicode provides remote control of equipments in several distant stations with continuous indications for each piece of apparatus controlled, over only two line wires, and also makes possible selective remote-motoring indications over same two wires used by supervisory control, as well as operation of number of remote stations in parallel on same two wires; most important feature of visicode is that it reduces line wire costs to minimum not possible with previous three- and four-wire designs.

Switchgear

METAL-CLAD. Guide for Specification Covering Metal-Clad Switchgear. *Nat. Elec. Light Assn.—Pub.*, no. 149, July 1931, 3 pp., 1 fig. Guide is primarily intended to serve as reminder of points to be covered when purchasing equipment and as indication of logical order in which they should be enumerated; five different unit standards are presented.

Synchronizers

AUTOMATIC. A Thermionic Automatic Synchronizer, F. H. Gullikson. *Elec. Jl.*, vol. 28, no. 7, July 1931, pp. 421-423, 4 figs. New synchronizer requires but five volt-amperes per transformer for its operation, which is well within limits of energy which can be drawn from potential devices, making transformers unnecessary; this makes possible automatic synchronization in some applications where it was not previously justified economically; synchronizer uses two thermionic tubes which, because they are in use only during synchronization, have life of five to ten years.

Telephone

AUTOMATIC. Dial Offices for Small Communities, F. T. Meyer. *Bell Laboratories Rec.*, vol. 9, no. 12, Aug. 1931, pp. 562-566, 5 figs. Adaptation of improved telephone equipment to smaller communities, especially those more or less isolated from larger operating centers, has been greatly facilitated by development of new dial office of step-by-step type; equipment is described in some detail.

The Bypath Automatic Telephone, E. P. G. Wright and J. H. E. Baker. *Post Office Elec. Engrs.—Jl.*, vol. 24, pt. 2, July 1931, pp. 116-124. Bypath system is universal automatic telephone system employing single motion switches (or uniselectors) of simple design; development of system has been carried out entirely in London and is outcome of unremitting research work extending over number of years resulting in production of system which, in opinion of authors, is superior to other step-by-step systems; in this class it achieves standard of efficiency hitherto unattained.

DIAPHRAGM MEASUREMENT. Recording Contour Gauge, E. C. Erickson. *Bell Laboratories Rec.*, vol. 9, no. 12, Aug. 1931, pp. 567-570, 6 figs. Equipment for measurement of quality and adjustment of diaphragm; photographic record of two diaphragms are given.

LONG DISTANCE. Speed of Service on Long Distance Calls, C. Bryon. *Telephony* vol. 101, no. 3, July 18, 1931, pp. 25- and 28-29, 1 fig. Average time required to complete toll call is 1.6 min. compared with eight min. in 1926; some principles for obtaining and maintaining speed of service. Paper before Annual Traffic Conference, III.

RELAYS. Characteristics of Strowger Relays—III, K. W. Graybill. *Telephone Engr.*, vol. 35, no. 7, July 1931, pp. 32-33, 3 figs. Various methods used to determine mechanical adjustment values of horizontal relays; reference tables governing these values.

REPEATERS. Repeaters for Two-Wire Toll Circuits, R. L. Case. *Bell Laboratories Rec.*, vol. 9, no. 12, Aug. 1931, pp. 579-584, 10 figs. Twenty-one type repeater employs but single amplifying element and is limited in its use by requirement that lines in opposite directions must balance each other; employment of balancing networks, and two amplifying element results in broader applicability of 22-type repeater; simplified schematic diagram of 22-A-1 repeater; loss-frequency characteristics and gain-frequency characteristics of equipment described are given.

Negative Impedances and the Twin 21-Type Repeater, G. Crisson. *Bell System Tech. Jl.*, vol. 10, no. 3, July 1931, pp. 485-513, 16 figs. Negative resistances and impedances; their properties and some devices by which they may be produced physically; certain properties of negative impedances when used as series and shunt boosters for amplifying speech waves in telephone circuits; description of circuit and properties of twin 21-type repeater.

STATISTICS. World's Telephone Statistics, January 1, 1930. *Bell Telephone Quarterly*, vol. 10, no. 3, July 1931, pp. 138-149, 7 figs. Statistical data, tables, curves and maps.

TESTING. Automatic Testing Equipment for Trunk Circuits, T. R. Lundius. *Bell Laboratories Rec.*, vol. 9, no. 12, Aug. 1931, pp. 589-592, 2 figs. To make sure that supervisory relays are functioning properly they are frequently tested, and since there are large numbers of them to simplify and quicken procedure, automatic circuits have recently been developed which operate relays under conditions more severe than are ordinarily met in service.

Television

PICK-UP. Television Direct Pick-up Camera, D. W. Short. *Electronics*, vol. 3, no. 2, Aug. 1931, p. 69, 1 fig. Novel method of "picking up" television images is made possible by means of direct pick-up camera; this device differs from indirect pick-up method or so-called flying spot equipment, inasmuch as image of person or object being televised is focused directly upon spiral number one of scanning disk.

Transformers

CONSTANT CURRENT. Simple Automatic Time Control for Constant-Current Transformers, W. H. Colburn. *Elec. World*, vol. 98, no. 5, Aug. 1, 1931, pp. 202-203, 3 figs. Control described has been devised to meet following operating requirements; start at predetermined time and continue to operate until cut out, at predetermined time; cut out and lock out individual transformer or main breaker in event of electrical failure in one or in totality circuit; etc.

EXTINGUISHING COILS. Determination of the Rating of Extinguishing Coils Which May Be Connected to Transformers, A. van Gastel. *Brown Boveri Rev.*, vol. 18, no. 8, Aug. 1931, pp. 251-259, 14 figs. Design analysis, diagrams, characteristics and equations.

Vacuum Tubes

CONSTANTS. Graphical Representation of the Three Constants of a Triode, I. Miura. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1488-1491, 2 figs. It is shown that three constants of triode, e. e., amplification factor, internal resistance, and transconductance can be represented by one point in equilateral triangle logarithmically scaled; as example, graph in which are plotted constants of 24 kinds of typical tubes now used in practise is given.

PENTODES. Performance of Output Pentodes, J. M. Glessner. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 8, Aug. 1931, pp. 1391-1405, 17 figs. Comparison of power output, distortion, power sensitivity, and a-c./d-c. power economy of group of experimental pentodes is made with corresponding triodes; apparatus and method of measuring are described; pentodes' a-c./d-c. economy and power sensitivity is considerably higher than that of corresponding triodes; harmonic distortion is found to be generally worse with pentodes; variation in power output with changes in load resistance, arbitrarily called "output distortion," is shown to be about same for both classes of tubes.

ULTRA SHORT WAVE. Tubes for Generating 18-cm. Waves. *Electronics*, vol. 3, no. 1, July 1931, p. 4, 1 fig. Photograph of tube used in transmission of radio phone communication across English channel by means of directive wave of order of 18 cm. published for first time.

VOLTAGE REGULATORS. Tube Voltage Regulator Eliminated Hunting Tendency, F. H. Gulliksen. *Elec. World*, vol. 98, no. 4, July 25, 1931, pp. 162-163, 2 figs. Thermionic type voltage regulator for d-c. generators has recently been developed, by which anti-hunting force should be proportional to rate of recovery of regulated voltage, and must be zero when regulated voltage is normal at any generator load; anti-hunting adjustment should be simple and independent of adjustment for regulated voltage and regulator response.

Watt-Hour Meters

BEARINGS. An Investigation of Problems Relating to the Use of Pivots and Jewels in Instruments and Meters, V. Stott. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 414, June 1931, pp. 751-756, 13 figs. Results obtained in investigation of problems arising in connection with use of pivots and jewels for bearings; means adopted for obtaining accurately shaped pivots and for measurement of pivots and jewels; method of measuring hardness and determining suitable radii of curvature.

CALIBRATION. Determining Large Three-Wire Lighting Meter Constants, H. W. King. *Elec. World*, vol. 98, no. 5, Aug. 1, 1931, pp. 201-202, 7 figs. Simple but infallible method of determining or checking dial constants in cases where self-contained meters with dial constant equaling one, may be used with current transformers and then have new multiplying constant assigned and marked on dial in meter shop.

Waves

ANALYSIS. High-Voltage Surge Testing, P. H. McAuley. *Elec. Jl.*, vol. 28, no. 5, May 1931, pp. 278-280 and 305, 10 figs. Analysis of laboratory data; interpretation of oscillograms; time lag of breakdown; obtaining time-lag curves from oscillograms; laboratory data required.

Welding

Twenty-Five Years of Electric Welding, P. W. Fassler. *Am. Welding Soc.—Jl.*, vol. 10, no. 5, May 1931, pp. 29-35, 8 figs. History of welding; fundamental thermal and electrical laws which have vital bearing on design of welding machines; butt welding; spot welding; relief welding; seam welding.

ARC. Automatic Arc-Welding: Its Advantages and Limitations, A. M. Candy. *Elec. Jl.*, vol. 28, no. 7, July 1931, pp. 415-417, 6 figs. General outline of process and equipment.

ARC—ATOMIC HYDROGEN. High Tensile Atomic Hydrogen Arc Welds in Alloy Steels, F. Ray. *Am. Welding Soc.—Jl.*, vol. 41-45, 11 figs. Welding procedure in making Flexo Disc expansion joint which consists of steel bellows constructed of corrugated steel discs welded together at their inner and outer peripheries; properties of weld.

BOILER MANUFACTURE. Attitude of Eleven Utilities Toward Welded Boilers. *Elec. World*, vol. 97, no. 21, May 23, 1931, pp. 955-957, 1 fig. N. E. L. A. prime movers committee has given welded boiler drums and tubes considerable study and A. S. M. E. boiler code committee is now engaged in formulating code that permits such construction; several utility executives and engineering or operating department heads were asked three questions treated later to ascertain possible trend of welded boiler acceptance and also what active cooperation might be expected from users in bringing about code acceptance.

PIPE LINES. Design for Welded Piping, A. G. Wikoff. *Am. Welding Soc.—Jl.*, vol. 10, no. 5, May 1931, pp. 26-28, 9 figs. Standard designs for various types of joints recommended for welded piping systems; developed by Linde Air Products Co.; open single vee butt welds; open square butt weld; closed single vee butt weld; welded coupling; butt weld with thin liner; special reinforced joints.

Welding Machines

ARC. The Burke-Scott Electric Welder. *Engineer*, vol. 152, no. 3939, July 10, 1931, p. 48, 2 figs. Although primarily intended for arc welding, it may be used for other purposes that call for similar operating characteristics; machine may be regarded as one in which main pole parts are split into two parts, one part being shunt-wound and other series-wound.

Welds

GAMMA RAY ANALYSIS. Inspection of Welds with Gamma Rays, G. E. Doan. *Am. Soc. Steel Treating—Preprint*, no. 34 for mtg. Sept. 21-25, 1931, 8 pp., 5 figs. Gamma-ray method gives adequate results for inspection of welds, according to tests made by author at Lehigh University; tests on good welds and bad welds revealed each kind without fail; not only were defects plainly visible in bad welds, but good welds were revealed as sound, in each case.

X-RAY ANALYSIS. X-Ray Inspection of Welds, H. R. Isenburger. *Am. Welding Soc.—Jl.*, vol. 10, no. 5, May 1931, pp. 17-21, 15 figs. Inspection methods and equipment of St. John X-Ray Service Corp., New York; diagram of exposure technique for small tubing inspection; diagram of fluoroscopic x-ray inspection; operating cost is $3 to $5 per hour.

Industrial Notes

A New Clip-On Ammeter.—Ferranti Electric, Limited, Toronto and New York, has developed a new instrument known as the Clip-On Ammeter, which may be used for determining the actual loading of transformers, for balancing secondary transformer loads on three-wire services, or for checking power consumers' loads. It will also be of value to electrical contractors and plant electricians in determining actual loads taken by individual motors, or balancing loads on different circuits or feeders. It consists of a split-core current transformer with the secondary connected to a high grade, well damped Ferranti milliammeter calibrated for direct reading in amperes. The operating handle is well insulated. Good accuracy is provided even at low currents because of the low burden of the meter, which is only 0.22 voltampere. This is a feature not found in any other typ eof such equipment.

This instrument affords a rapid and convenient method of measuring the current in any a-c. leads or bus-bars without disconnecting them for the insertion of the usual current transformer or ammeter leads. The meter has a double range, one scale being 0-100 amperes and the other 0-500 amperes. A switch on the meter changes the reading from one scale to the other. The instrument is light and can be operated easily with one hand.

Ohio Brass Promotes H. H. Crow.—Announcement has been made by the Ohio Brass Company, Mansfield, Ohio that H. H. Crow, with headquarters at the New York office, is now in charge of its sales territory in upper New York state. He will handle the sale of high tension insulators and electrical porcelain to the power companies in that locality.

Oil-Blast Principle Applied to Low Capacity Breakers.—The General Electric Company has announced a new line of triple-pole circuit breakers for outdoor service designated Type FKO-60. These breakers can be furnished mounted on self-supporting steel framework or for pole-mounting, and for manually-, solenoid-, or motor-operated requirements. The interrupting rating is 50,000 kva., equipped with blade-and-finger contacts, using the plain-break principle of arc interruption. Each pole is in a separate oil tank. The Types FKO-60B and FKO-60C breakers have interrupting ratings of 100,000 and 175,000 kva. respectively. They have separate oil tanks for each pole and operate on the oil-blast principle. An insulating chamber is fitted within each tank. In each chamber an exhaust port is located adjacent to one of the breaks in each phase. A pressure is set up within the oil by the arcing of the contacts. The only vent for this oil under pressure is through the exhaust port.

An Improved Type of Switchboard Matting.—The Diamond Rubber Company, Akron, Ohio, announces an improved insulation matting for use as a protection to the operators of power switchboards, that is guaranteed when tested in accordance with the methods prescribed in American Society For Testing Materials Specification D-178-24, to withstand the following tests: Voltage Test—Thicknesses of 1/8", 3/16", 1/4" and 3/8" will withstand a potential of 15,000 volts for one minute when tested between electrodes consisting of rectangular metal sheets or plates 9" x 15" in size, or of equivalent area. Dielectric Test—When a section of the matting is tested in air between disc electrodes 2" in diameter, it is guaranteed to withstand the following voltage: 1/8" thickness 20,000 volts; 3/16" 30,000 volts; 1/4" 40,000 volts; 3/8" 45,000 volts. The matting is made with six laminations of high grade rubber, and a ply of fabric to give additional strength.

New Protective Feature for Street Lighting Lamps.—The Westinghouse Lamp Company announces the development and perfection of a protective short-circuiting device, the "Inbuilt Cutout" which, supplemental to the regular construction, may be built into the base of Mazda incandescent lamps designed for burning on series circuits. In addition to the greater convenience of relamping after burnout, lamps with Inbuilt Cutouts possess two notable advantages—

First, it serves as a completely reliable means for quenching the arc which, upon burnout of the filament, has occasionally persisted. In rare instances such arcs have continued to a point where the socket and even the post top has been destroyed. Second, because it operates with lesser variation from designed breakdown voltage than is the case with short-circuiting filaments, discs or materials heretofore employed, the Inbuilt Cutout makes it possible successfully to operate small series circuits of only a few lamps. This is sometimes of considerable advantage in supplying street lighting service for newly added, outlying territories.

Gilbert Gislason Joins U. S. Magnetic Products Corp.—According to a recent announcement, Gilbert Gislason has been appointed special representative of the Great Lakes District and also in upper New York State, for the U. S. Magnetic Products Corp., Lock Haven, Pa., manufacturers of coil windings, solenoids, transformers, etc. Mr. Gislason was previously connected with the Easton Coil Co., Easton, Pa., and in his new connection he again becomes associated with N. L. Dinion. A few months ago Mr. Dinion resigned as president of the Easton Coil Co., to become vice-president of the U. S. Magnetic Products Corporation.

Kester Solder Opens Canadian Plant.—The Kester Solder Company has announced the opening of a new plant at Brantford, Canada, on September 15. The plant will be operated under the name of Kester Solder Company of Canada, Ltd. Other factories are located at Chicago and Newark, N. J.

Trade Literature

Lava.—Bulletin, 24 pp. Describes lava and magnesia specialty insulation. This material has very high dielectric strength and will withstand extremely high temperatures. It is widely used by electrical manufacturers as an insulator in many forms. Lava products are produced with the same degree of accuracy and interchangeability as those of a screw machine and without the necessity of first making dies or molds. American Lava Corporation, 27 William St., Chattanooga, Tenn.

Motor Starter.—Bulletin, 4 pp. Describes a new EC&M oil-immersed starter for motors of large horsepower. Like the No. 1 type ZO starter, this larger starter is a self-contained unit, totally enclosed in a heavy pressed steel case with oil-immersed main and control circuit contacts, and vapor-proof overload relays. If desired, installation of such starters can safely be made alongside the motors controlled. The Electric Controller & Mfg. Company, 2700 East 79th Street, Cleveland, Ohio.

Celoron Gears.—Bulletin, 28 pp. Describes Celoron silent gears and illustrates their application in various types of machinery. Continental-Diamond Fibre Company, Newark, Delaware.

Trimming Board.—Bulletin. Describes a new and improved cutter for use in drafting rooms, engineering schools, and for cutting insulating materials or other sheet materials. An automatic hold-down clamp works through the movement of the 26-inch blade in advance of the shearing. No wood is employed in the construction, the top being of Bakelite with engraved quadratic lines one inch apart over its entire surface. Bosch Products Company, San Francisco, and 370 Lexington Ave., New York.

WITH 25 years' professional engineering experience in the U. S. A. and a recent eighteen-month engagement in the U.S.S.R., a native of Russia gives some interesting sidelights on that country's much discussed industrial development. (*See p. 883-5.*)

EDISON, the newsboy, telegrapher, inventor, creator of innumerable devices and processes underlying in no small way the modern commercial and industrial development of the world, has been cited for his Final Reward. His life's work has had great effect on pure and applied sciences. His dominating motive was creation. His indomitable will and devotion to his work will stand as historical monuments to inspire and to encourage those who follow. The Institute with the world mourns his passing. (*See p. 904-7.*)

Field Studies of Arcing Faults on Power Lines

Experimental studies of arcing faults on a 75-kv. transmission system indicate that a lightning flashover is most likely to develop into a power arc when power current is flowing past the flashover point, when normal-frequency voltage is increased, or when line insulation is decreased.

By
J. R. EATON Consumers Pwr. Co. Jackson, Michigan

Associate A. I. E. E.

A DISCUSSION of the continuity of service which can be maintained on a power system frequently involves the consideration of power arcs. In spite of the acknowledged importance of arcs in the operation of power systems, there is but little available experimental information concerning the causes of power arcs which follow surges, the characteristics of arcs, or the resulting effects of arcs. The results of cooperative experimental investigations made by the Consumers Power Company, Jackson, Mich., the General Electric Company, and the joint development and research subcommittee of the National Electric Light Association and Bell system, to study the character of arcing faults are discussed here.

Factors Governing the Power-Arc Development

Operating data presented in the past few years have indicated that lightning frequently may cause sparkover of transmission-line insulators without producing a power arc. Although the spark and the arc are quite different in nature, there is no sharp line of demarcation between the two, and the transition from one to the other is but little understood.

To investigate experimentally the factors governing the transition of an impulse flashover into a power arc, impulses from a 1,500-kv. lightning generator were applied to a transmission-line conductor energized to ground through a transformer bank. The line insulation was such that in every case flashovers occurred at a predetermined test tower where the amount of insulation was varied at will. The length of the transmission line beyond the test tower could be changed from a few feet to 35 mi.; with the 35-mi. line the total charging current of the three-phase line flowed past the flashover point, thus simulating a load on the line.

The curves shown in Fig. 2 give the results of 278 tests in which the applied 30-cycle voltage, the flashover distance, and the condition as to whether or not current was flowing past the flashover point were varied. The point on the 30-cycle voltage wave at which flashover occurred was governed merely by chance. These curves show that for a given electrode spacing and excitation voltage, power-arc follow-up is more likely to occur when current is flowing past the sparkover point. The explanation for this probably lies in the fact that current is immediately available for maintaining the power arc without having to overcome the inductance of the circuit. The curves show also that for a given electrode spacing, the possibility of power-arc follow-up is dependent upon the value of normal frequency excitation voltage.

During 66 of the tests oscillograms of voltage and current in the transmission line were obtained, from which could be determined the point on the 30-cycle voltage wave at which flashover occurred. Results of these tests showed that a high percentage of flashovers occurring near the 90-deg. point of the voltage wave resulted in power arcs. From a further analysis it was found that this grouping of tests near the 90-deg. point was very definite for tests in which current was flowing past the sparkover point, but when there was no current in the line the points were fairly well scattered.

From "Experimental Studies of Arcing Faults on a 75-Kv. Transmission System," (No. 31-102) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

It is possible that on systems having large connected generating capacities carrying heavy loads, with the consequent immediate availability of large currents, the per cent of sparkovers developing into power arcs may be much higher than is indicated by these tests.

Characteristics of Power Arcs

In connection with relaying and short-circuit computations it is desirable to know, under certain fault conditions, something regarding the characteristics of power arcs. From the results of some 30 tests made under various conditions, some information has been obtained regarding the variations in arc resistance, wave shape, persistence, length, and voltage. In general, the arcs were formed in three types of circuits—resistive, capacitive, and inductive—at either 75- or 7.5 kv. and with initial currents varying respectively from 8 to 60 and from 200 to 800 amperes peak. Connections for these circuits are shown in Fig. 3. Measurements were made by means of a magnetic oscillograph through the use of shunts for current measurements and resistance potentiometers of the water-hose type having a resistance of approximately 500,000 ohms for voltage measurements.

It is known that the resistance of a d-c. arc is not constant, but is dependent principally upon the arc current and length. Because of the variation in an alternating current over a cycle, it is to be expected that the arc resistance would vary over a cycle, and if the length of the arc changed from cycle to cycle, a change in the limits of this cyclic variation should be noted for succeeding cycles.

Curves of Fig. 4 show that through a cycle, the resistance varies over a wide range, being high for low values of current and low for high currents. The minimum arc resistance for the cycle near the point of extinction of the arc (28th cycle) is larger than the corresponding value for the cycle near the start. This difference arises from the lengthening of the arc and the decrease in current. The curves in Fig. 5 illustrate this change in instantaneous resistance with respect to time, and in general show an increase with the passage of time until the arc was extinguished. In the early stages of the arc the increase in resistance is caused by the lengthening of the arc; as the resistance increases it becomes a larger percentage of the circuit impedance and limits the arc current. The decrease in arc current still further increases the resistance, so that finally the arc is extinguished. The curves described are for a test made in a resistive circuit and are of the same nature as those for the capacitive and inductive circuits.

The question as to the phase relation between the arc current and arc voltage frequently has arisen. Although the oscillograms indicate that for every test the arc current and voltage have simultaneous zeros, the apparent power factor of the arc may not be unity if the variations of arc current and voltage are not sinusoidal. An analysis of the oscillograms for the tests in which the arc current varied from 8 to 60 amperes peak showed that the apparent power factor of the arc varied from unity near the start to 0.75 near the point of extinction. For the high-current tests (200-800 amperes peak) the apparent power factor was practically unity.

Changes in wave shape of the arc current and arc voltage are attributable to the variation in arc resistance over a cycle. Near the start of the arc the resistance is not of sufficient magnitude to affect the current, but the arc voltage is affected by the variation in resistance and tends to become a square wave. Near the point of extinction of the arc, where the resistance is greatly increased, the current is greatly decreased and distorted and the voltage approaches in magnitude and wave shape the open-circuit voltage.

The records obtained when the arc was formed in the three types of circuits (resistive, capacitive, and

B—Instantaneous resistance for tail voltage
C—Instantaneous resistance for peak voltage
D—Ratio of peak current to peak voltage

inductive), indicate that only in the case of the capacitive circuit did the arc restrike following the first extinction at current zero. Although it was not possible to duplicate exactly the conditions of wind, wave shape, and current for these three types of circuits, apparently if arcs are formed under identical conditions in these three types of circuits, the capacitive arc will show the greatest tendency to persist because of its restriking after the first extinction. The explanation for the restriking of the capacitive arc lies in the fact that the charge trapped on the equivalent condenser in the circuit causes the voltage across the arc to rise to twice normal immediately following arc extinction.

A fairly accurate determination of the length of the arc was possible by combining the measurements from two motion picture cameras which were set up at right-angles to photograph the arc. Arc voltages which corresponded in time to the measurements of length were obtained from the oscillograms. It was found that if the peak voltage per foot of arc length were plotted against current, there was a very definite grouping of the points for currents above 100 amperes peak at 300 peak volts per foot of arc length. There was no definite grouping of the points for currents below 100 amperes peak.

Overvoltages Due to Arcing Grounds

Opinions vary rather widely as regards the maximum overvoltages which can be developed on an isolated-neutral transmission system at the time of an arcing ground, according to whether such opinions are based upon theoretical considerations, on laboratory tests, or upon limited operating data. From the tests on a part of the isolated-neutral transmission system of the Consumers Power Company information on the nature and magnitude of such overvoltages was sought.

In Fig. 6 is shown a schematic diagram of the 75-kv. three-phase system utilized. The transformers were connected either Δ/Δ or *Y*/*Y* with the low-voltage neutral grounded or isolated, and the length of line was varied up to 134 mi. Faults involving arcs to ground were produced on phase *M* conductor at different points on the line, which was open at the far ends. These faults were initiated in different ways and were made through both high- and low-external resistances. At the time of the fault the phase voltages to ground and the arc current were recorded on magnetic-type oscillographs as previously mentioned. Surge-voltage recorders were connected to the three phases at the generating end and at the open end of the transmission line to supplement oscillographic measurements of voltage.

The highest sound phase overvoltage recorded by the oscillographs in 64 arcing ground tests made on the isolated system was 2.8 times normal; the maximum surge-recorder measurement was 3.0 times normal. In every test the faulted phase voltage was less than the sound-phase voltage and in no case were the surge-recorder measurements more than 15 per cent higher than the corresponding oscillographic records. In a majority of the tests the maximum overvoltage occurred during the first cycle of the fault and was from 10 to 15 per cent higher on phase *B* which led the faulted phase voltage, than on lagging phase *T*. Average values of the highest overvoltages recorded during the fault for all the tests were 2.35 and 2.13 times normal for phases *B* and *T* respectively.

Oscillograms shown in Fig. 7 illustrate the nature of the transient changes at the time of a fault as they occurred in a large number of the tests. Both the striking and extinguishing of the arc take place according to normal (30-cycle) frequency. When the arc strikes, the faulted phase voltage is reduced to zero and a highly-damped standing wave follows the traveling wave set up on the faulted conductor. This standing wave is evidenced by oscillations in the wave of arc current and in the voltage wave recorded at the open end of the line (see oscillograms 82-A and 82-C). When the fault was at one end of a single-line system which was varied in length up to 94 mi., oscillograms showed that the frequency of these oscillations, called oscillatory frequency, corresponded to the free or natural period of oscillation of the line.

It may be seen in Test 82 of Fig. 7 that similar oscillations of low amplitude also are present in the voltage waves of the sound phases *B* and *T* at the striking of the arc. These small oscillations, however, do not occur at the highest crest of the voltage waves and add nothing to their maximum values. The overvoltage is essentially a fundamental-frequency phenomenon and is made up of (1) a change in impressed voltage from that of line-to-neutral to that of line-to-line without going through an oscillation of appreciable amplitude, (2) a d-c. transient which shifts the zero of the normal-frequency wave, and (3) in some cases a harmonic of lower order. Surge recorders testified that no transients of higher magnitude were present. In the case of an unstable arcing ground, such as that shown in Test 71, the current restruck from zero usually every half-cycle, when the voltage was equal to or less than its normal crest value, and resulted in no building up of overvoltages.

A high-resistance arcing ground fault such as an intermittent tree ground, even if it persists for some time, was found to limit the shift of the system neutral and hence to tend to limit the magnitude of overvoltages produced. The highest measured overvoltages, nearly three times normal, occurred for tests on the longest line (134 mi.) when the arc happened to strike just beyond the crest of the voltage wave. Changes in transformer connections, fault location, and method of starting the arc, did not materially change the nature or magnitude of the overvoltages.

Why Apply Science?

Most of the material things which man wishes to do can be done with certainty and repeated with assurance only through the application of scientific information. This is the fourth article of The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"

By
H. E. HOWE
Editor, Industrial and Engineering Chemistry

HOW OTHER than through applied science could one discover why clean scab-free potatoes can be grown in some fields and not in others? It has been learned that the hydrogen-ion concentration of the soil is a determining factor, and simple means have been devised which enable an unscientific man to make the necessary tests, within limits, and choose soil of proper acidity to guarantee scab-free potatoes. A very small quantity of selenium in copper renders the copper less suitable for the transmission of electric impulses than if the copper were pure. Without science, how could such a small difference have been discovered? It is a further application of science to remove effectively the interfering selenium; and a still further utilization of science to find ways for employing the by-product selenium. It is another triumph of science that the use of selenium in certain types of glass has given us spectroscopic red glasses so necessary for signal lamps which must show red under all circumstances and to all eyes.

When, again through applied science, it became known how to use chlorine for bleaching textiles, it was not realized how quickly the chlorine will do its work under controlled conditions. Thanks again are due to science for learning these conditions and for determining what took place, with the result that under some circumstances thorough bleaching can be done in 45 seconds without detriment to the fiber.

There are uncounted examples of similar occurrences in industry, where a lack of uniformity in finished products would be immediately noticeable without the control possible only through applied science. Small differences in time, in temperature, in velocity, and in concentration, make for the difference between success and failure. It is science that determines what these limitations are, and again it is science that makes possible an adherence to a prescribed procedure which through experimentation has been found to give the desired results.

When it is remembered that, as Huxley said, science is organized common sense, the question "why apply science" answers itself. The life of a normal man is made up of little conquests with which he always is striving to achieve some objective. Most of these efforts involve materials, and it is with these same materials that science concerns itself.

The chances for having a thing do what one wishes are increased immeasurably as accurate knowledge is acquired, not only of what takes place, but of just how and why events occur as they do. When such details are known, happenings often can be controlled to a nicety. It is this control of natural processes that applied science makes possible; without such control there is loss, disappointment, and failure.

Fruitful application of science by no means is confined to industry. It has its most useful work today in the field of health and disease. There is perhaps no organism so delicately balanced as the human body; the mere difference of where an atom is placed in a molecule leads to so great a divergence in the characteristics of that molecule as profoundly to affect the human body. Adrenalin exists in two forms; one of these the mirror image of the other. One molecule may be said to be left-handed and the other right-handed. One has fifty times the potency of the other. Some of our best known germicides have been devised with a similar knowledge of the effect of small differences. Hexylresorcinol is much more useful than would be a compound with five or one with seven of these groups.

Other examples of comparatively small differences are found in carbon monoxide—a subtle, deadly poison—and carbon dioxide—a highly useful industrious gas. The difference is a single atom of oxygen. Mercury compounds show similar differences between the one use as a disinfectant and the other as a medicine. So long as such small differences are vastly important there is obvious need for the application of science, for without science these differences cannot be determined and the resulting information utilized.

Through its thousands of years, the race has learned much by bitter experience. However, even in the oldest industries, like bread making, tanning, and brick making, things have occurred beyond control until science stepped in to determine cause and effect, and to indicate conditions under which control may be maintained and success thereby assured. Most of the material things which man wishes to do can be done with certainty and repeated with assurance only when based upon scientific information. Progress in the oldest arts as well as in the newest can be measured accurately by the extent to which science is applied.

Editor's Note: Pursuant to the invitation of The Engineering Foundation, the editors will be happy to receive comments, suggestions, criticisms, or discussions pertaining to this or the other articles published in this series.

Electric Analogs for Difficult Problems

When the mathematical solution of a problem is so difficult as to be impracticable it sometimes is possible to obtain the desired answer from the behavior of an analogous electric circuit. This article presents an analog of "coulomb friction," and demonstrates the application of this analog to the previously unsolved problem of the torsional-vibration damper.

By
H. H. SKILLING
Associate A. I. E. E.

*Stanford University
California

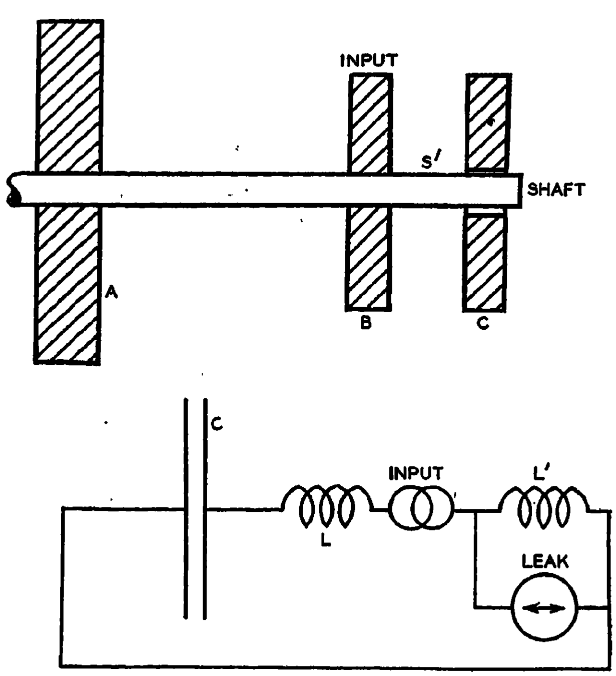

Fig. 1. (Above) mechanical system schematically representing the Diesel engine; (below) the electric analog of this mechanical system

SOLUTION of the equation of motion for the torsional-vibration damper represents one of the mathematical problems which is extremely difficult to solve. Almost endless complications are involved on account of the peculiar combination of vibratory motion and friction which the problem contains. An approximate solution can be arrived at by introducing several assumptions, but this is not entirely satisfactory; in the more intricate cases, approximate solutions are of no value at all. In order to predict the effectiveness of new designs, mechanical models sometimes are built and tested. Difficulty often is experienced, however, in the construction of these models, and in addition, the results obtained have been found to be somewhat uncertain.

In this article is proposed a method of solution wherein electric analogs are set up for the various types of mechanical motion involved. An electric circuit can then be set up with constants analogous to the mechanical characteristics of the apparatus being studied. The principal advantage in treating the problem in this manner is in dealing with a system easily put together and altered, and with quantities easily metered. Although the analogous method in general is not new, difficulty has been experienced previously in representing mechanical friction electrically. In the present investigation this obstacle has been overcome by the use of gaseous conduction tubes.

The torsional-vibration damper is in effect a flywheel that fits loosely on a shaft. A common application is on the crank-shaft of a Diesel engine, where there is danger of torsional stress in the shaft becoming extremely large because the natural frequency of oscillation of the shaft may be the same as the firing frequency of the cylinders. The damper flywheel is placed on the shaft at the point where torsional vibration is greatest; it is not keyed fast but turns with the shaft because of the friction between the two. When rapid torsional vibration of the shaft exists, the friction force is not great enough to accelerate the flywheel as rapidly as the shaft; hence the shaft slips within the flywheel and in so doing dissipates sufficient energy to prevent resonant oscillation of the shaft. In actual design, the damper although simple is not so elementary as this account has indicated. A detailed description may be found in a paper by Den Hartog and Ormondroyd (*A. S. M. E. Trans.*, Vol. APM-52-13, p. 133) which also treats its action by an approximate mathematical solution.

With ordinary dry friction—so-called "coulomb friction"—which is involved in the torsional-vibration damper, the frictional force depends upon the nature of the rubbing surfaces; also upon the force holding them together, but not upon velocity. An electric analog for this application must therefore produce a constant voltage drop, variable at will but independent of the amount of current flowing.

A mechanical system which is the practical equivalent of a Diesel engine may be seen in Fig. 1. The main flywheel is shown at A; moment of inertia of the pistons, cranks, and other moving parts is represented by another flywheel B; the damper flywheel which fits

---

*Written especially for ELECTRICAL ENGINEERING and the A. I. E. E. TRANSACTIONS based upon research work carried on by the author at Massachusetts Institute of Technology, during 1929-'30. *Not published in pamphlet form.*

loosely on the shaft is shown at *C*. Input torque from the cylinders, which may be considered as a steady torque with a superposed alternating torque, enters the system at the pistons. Any load on the engine will be applied to the left of the main flywheel.

Table I—Mechanical-Electrical Analogies

Mechanical quantity	Electrical quantity
Torque	Voltage
Velocity (angular)	Current
Displacement (angular)	Charge
Moment of inertia	Inductance
Elastance (torsional)	Elastance
Mechanical hysteresis	Resistance

The electrical analogy to this mechanical arrangement is shown also in Fig. 1 where, with the exception of friction between the shaft and the damper flywheel, the electrical quantities used are as shown in Table I. Analogous to the shaft is condenser *C*; analogous to the piston flywheel *B* is inductance *L*. These cooperate to form the oscillating system, since the main flywheel s so large that for the present it can be considered infinite and therefore impassable by any vibrations. The damper flywheel *C* is represented by the inductance *L*, but because of its looseness on the shaft a shunt must be connected around the inductance to make the analogy complete. In this shunt is the apparatus which, to be analogous to friction of the flywheel on the shaft, must prevent current from flowing until a certain voltage is reached, and then permit current to pass without any further increase of voltage.

The peculiar property of constant voltage drop is possessed by a mercury arc; it is also characteristic of glow discharge under special conditions. For this investigation raytheon gaseous conduction tubes were employed. Two tubes were used, one to pass current in each direction; the voltage drop in the tubes as they were connected in this case was 85 volts independent of current. In series with each tube was a source of potential which either added to or subtracted from the 85-volt tube drop depending upon other conditions. For the input to the circuit an alternator was used the speed and voltage of which could be varied over an extremely wide range; its resistance, together with that of the rest of the system, was small. For mechanical hysteresis losses in the elastic parts, and for any viscous friction that may exist, resistance is sufficiently analogous to permit its use.

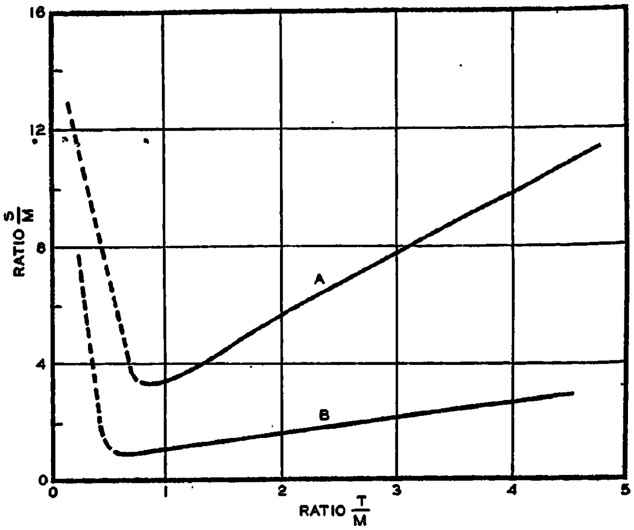

Fig. 2. Performance curves for the torsional-vibration damper as determined by electrical anal gy. (A) With rigid damper shaft, (B) with lastic damper shaft

The validity of the complete analogy may be seen from the differential equations of the two systems which are adapted from Den Hartog. For the mechanical system,

$$I \frac{d^2 \alpha}{d t^2} + I' \frac{d^2 \alpha}{d t^2} + k \alpha = M \sin \omega t$$

when the damper flywheel is not slipping, and

$$I \frac{d^2 \alpha}{d t^2} + k \alpha \pm T = M \sin \omega t$$

when this flywheel is slipping.

I = moment of inertia of system being damped
I' = moment of inertia of damper flywheel
k = elastance of shaft
α = flywheel displacement from neutral
$M \sin \omega t$ = input torque as a function of time

The analogous electrical equations, when the shunt is not working and when it is, are respectively,

$$L \frac{d^2 q}{d t^2} + L' \frac{d^2 q}{d t^2} + \frac{1}{C} q = e \sin \omega t$$

$$L \frac{d^2 q}{d t^2} + \frac{1}{C} q \pm v = e \sin \omega t$$

All terms are well known except *v*, the voltage drop in the leak, which is added or subtracted depending upon the direction of the current. The analogy of corresponding terms, displacement, and charge, for example, may be seen to agree with Table I.

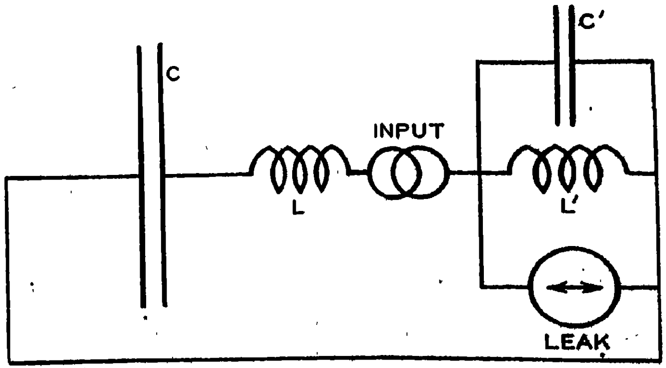

Fig. 3. Electric anal g f the torsional-vibration damper with elastic damper shaft. Compar Fig. 1

The purpose of making a detailed study of damper performance, whether by mathematics, model, or analogy, is to determine whether a particular damper is so proportioned as to prevent dangerous stresses in the shaft. Momentary stresses in a shaft are exceedingly difficult to measure, but the analogous voltages across the condenser in the electric circuit may be read quite easily on a crest-reading voltmeter; thus for any given combination of quantities and dimensions an indication of maximum stress is obtained immediately by simply reading that meter.

The crest voltage of condenser C (Fig. 1) is analogous to the maximum torque in the shaft and will be designated by S; analogous to the torque required to slip the shaft inside the damper flywheel, is the voltage drop in the leak which will be denoted by T. Results of a study by such analogy may be plotted showing S as a function of T, where curves similar to those of Fig. 2 will be obtained. If the value of S at the lowest point of the curve represents a safe stress, the damper is large enough to be useful; the value of T corresponding to this minimum value of S gives the optimum adjustment for tightness of the damper flywheel.

To avoid changing back and forth from mechanical to electrical units, it is well to avoid absolute values of quantities. Relative values need not be so transformed. Let M be the amplitude of the alternating input torque; instead of plotting S as a function of T, S/M may be plotted as a function of T/M. This scheme involves neither volts nor foot-pounds but only ratios, the ratio of voltage to voltage being of course numerically equal to the analogous ratio of torque to torque. The scale of the electrical model is equally unrestricted; only the proper ratios between parts need be specified. The frequency of the input voltage is of course the frequency causing the most severe stress; in the simple mechanical system the crucial stress will occur when the frequency of firing is the same as the natural frequency of the vibrating system.

As a typical example, assume a damper with moment of inertia of the damper flywheel equal to the moment of inertia of the system being damped. In the analog any convenient capacitance and inductance may be used to represent C and L (Fig. 1), but they must be resonant at some frequency attainable by the alternator used for *input*. The inductance L' equal to L is then added, and the vacuum-tube leak is connected across L'. The input voltage is adjusted to any convenient value, and the voltage drop in the leak circuit made comparatively large (for instance, 15 volts input and 85 volts drop in the leak). Now, as the frequency of the input voltage is varied, the crest voltage across condenser C will rise to a maximum and then decline. The maximum value of this voltage (in this particular case about 208 volts) is analogous to the maximum torque in the engine shaft. Dividing this by the maximum value of the input voltage, (about 21.2 volts) and the result S/M is about 9.8; divide the 85-volt drop also by 21.2 and the quotient, which is 4, is the value of T/M. By varying the leak and input voltages, enough points can be determined to give curve A of Fig. 2. This curve gives the whole story of the operation for this particular damper. Moreover, it gives the entire story of operation for all dampers having the same moment of inertia as has the system being damped. In present practise, however, a damper has from one-fifth to one-tenth the amount of inertia of the system being damped, and S/M is proportionately larger.

So far, the damper has been considered as being applied to the simplest possible vibrating system. This simple system may be solved mathematically, although with some difficulty if approximations are avoided. Accordingly, this case was used as a general check on the method, and the results were compared with Den Hartog's computed values; agreement was so close as to be within the limits of experimental error.

With the more complicated systems, however, solution by analogy is of far greater value. When the elastance of that part of the shaft labelled S' (Fig. 1) is considered, a mathematical solution is out of the question; in the analog a condenser of the proper size is simply shunted around L', and the solution is as simple as before. The study of this circuit disclosed an interesting and important relationship that previously was not recognized. As it is a typical analog, it will be used as a further example of the application of the method.

The circuit used with C' representing the elastance of the damper-shaft is shown in Fig. 3. The elastance of condenser C' must bear the same proportion to condenser C as elastance of the damper-shaft does to the main shaft. Now as the input frequency is varied, the voltage measured across C no longer has one maximum, but three. The reason for this is apparent from the diagram, since there are now two resonant parts of the circuit, consisting of (1) C and L and (2) C' and L'. At some definite frequency the reactance through C and L in series is zero; at two additional frequencies the reactance of the complete circuit is zero. However, if the natural frequency of C' and L' is the same as that for C and L, when the reactance through C and L is zero, the reactance through C' and L' is infinite; thus the circuit current under these conditions is small and one maximum eliminated. The other two maxima, one falling at a higher and one at a lower frequency, must be prevented from becoming serious by the action of the leak.

Experiments with this second analog showed that the damper is much more effective with an elastic damper-shaft than it is with a rigid shaft as in the first case. When the damper flywheel has one-fifth the moment of inertia of the system being damped, and when the damper-shaft is one-fifth as stiff as the main shaft, the analog method gives results as shown in curve B, Fig. 2. To make due allowance for the light weight of the damper, all ordinates have been multiplied by the ratio of moments of inertia (one-fifth); this makes the curves comparable to those of Den Hartog and Ormondroyd if a factor of $1/\pi$ is introduced into the vertical scale.

Since the primary purpose of this article is to point out the merits of the electrical means of solution, no particular attention is given to the mechanical merits of this new design of damper. Certain relationships were discovered by study of the analog, however, which seem worthy of mention. The "elastic damper-shaft" is not in the nature of a spring, for a shaft one-fifth to one-tenth as rigid as the main shaft of a Diesel engine is needed. The torque on the damper-shaft never can exceed T, the slip torque of the damper, and the shaft may be designed accordingly. The smaller the damper, the more effective will be a proper damper-shaft in improving its performance.

In conclusion, the principal advantages to be gained by the use of the electric analog are that (1) it shows the extent to which an approximate mathematical solution may be trusted, and (2) it offers a new method of approach to designers of dampers and other frictional devices. It is particularly useful in the study of new designs and at present there appears no limit to the possible applications of the method.

Power Equipment at KDKA's New Station

By
R. L. DAVIS
Associate A. I. E. E.
Westinghouse Elec. & Mfg. Co., Chicopee Falls, Mass.

Power for the two new high-power radio transmitters housed in KDKA's new quarters is obtained from a special 1,500-kva. outdoor substation. Included in the power equipment is a twelve-phase, 900-kw., 30-kv., mercury-cathode tube rectifier, the largest of its type yet built for radio.

THE NEW KDKA radio station at Saxonburg, Pa., has been designed not only for high-power broadcasting but also for experimental work dealing with the development of super-power transmitters. Two complete and independent high-power transmitters are involved, both being housed in the same building. One of these normally is operated at 980 kc. using the familiar signature KDKA, while the other is planned for higher frequency work. A station of this nature quite obviously required equipment considerably larger than that found in any ordinary broadcasting station. This is especially true of the power supply apparatus, among which the larger of the two main rectifiers is the largest high voltage unit ever constructed for such use.

Power is obtained from a 1,500-kva. outdoor substation about 700 ft. distant from the station building. This substation is fed from a 25-kv. loop circuit with relays and breakers so arranged that in case of trouble any faulty portion of the loop will be disconnected automatically without service interruptions on other portions. From the low voltage side of the transformer bank, power is carried to the station building over two three-phase 2.5-kv. armored cables laid directly in the ground.

MAIN RECTIFIERS

Both main rectifiers are of the polyphase mercury cathode type and operate directly from the 2.3-kv. three-phase supply. The larger rectifier has a rating of 900 kw. at 30 kv., and employs six 190-kva. single-phase transformers to provide the proper voltage and phase relations for twelve-phase rectification. (See Fig. 1.) Special connections are employed on the supply side of these transformers, since a Y-connection with floating neutral is undesirable for rectifier service.

Three of the transformers are connected in delta and the other three are carried across this delta from each apex to the midpoint of the opposite side, a tapped primary winding being used to give the required voltage relations. All six transformers are provided with two separate high voltage windings; these are connected to form four Y's, each of which is connected to one multi-anode mercury cathode rectifier. The d-c. outputs of the four tubes are connected in series so that while rectification takes place in four three-phase units, the result is the same as though a single high voltage multi-anode tube of twelve phases were employed. Connecting the outputs of the four tubes in series in this manner also requires only a moderate

Based upon "Power Equipment at New KDKA Station" (N . 31-67) presented at the A.I.E.E. Middle Eastern District meeting, Pittsburgh, Pa., March 11-13, 1931.

inverse peak voltage per tube in spite of the unusually high d-c. voltage developed.

The smaller, or 450-kw. 20-kv. rectifier, is similar to the larger one except that only three single-phase transformers are employed thus providing for six-phase rather than twelve-phase rectification. In both cases untuned filter circuits consisting of large iron-cored reactors and banks of high voltage condensers are employed to smooth the rectifier output.

Adjustment of the d-c. voltages developed by the rectifiers is accomplished by means of three-phase induction regulators designed to operate over a range of 100 per cent above and below line potential. With this arrangement the applied a-c. potential thus may be varied from 0 to 4.6 kv. Both regulators are motor operated and are remotely controlled from the operating room. The output of both rectifiers is controlled by air-break contactors similar to those used in mine hoist control, and which operate directly in the 2.3-kv. supply circuit. Both a-c. and d-c. overload relays are provided to shut down the equipment in the event of trouble necessitating the removal of plate voltage. For safety to operators the contactor control circuits are interlocked through switches on doors giving access to high voltage circuits. An oil circuit breaker manually operated from the main switchboard also is provided for each rectifier.

MERCURY CATHODE TUBES

Tubes used in the main rectifier are of the glass envelope mercury cathode type (see Fig. 2) and are somewhat similar to ones formerly used for operating d-c. series arc light circuits. The tubes are fully immersed in oil, each being housed in a separate tank and mounted in a cradle by means of which it can be removed readily. (See Fig. 3.) All necessary connections are made when the cradle slides into place, thus permitting tube changes to be made conveniently. For interchangeability, tubes of the same rating are used in both main rectifiers.

In addition to the three main anodes, the tubes are equipped with two small sustaining arc anodes, and one starting mercury anode. Automatic tilting mechanisms controlled from a push-button station are provided for starting the sustaining arcs. This mechanism functions in from one to two seconds, after which full operating plate potential may be applied immediately. Very little energy, about 120 watts per tube, is required to operate the sustaining arcs. This is small compared to the filament heating requirements of a filament type tube rectifier for furnishing the same power output. While not commonly employed for radio power apparatus, nevertheless mercury-cathode rectifier tubes have desirable characteristics particularly in installations such as these where the use of filament tubes would be prohibitive on account of the number required.

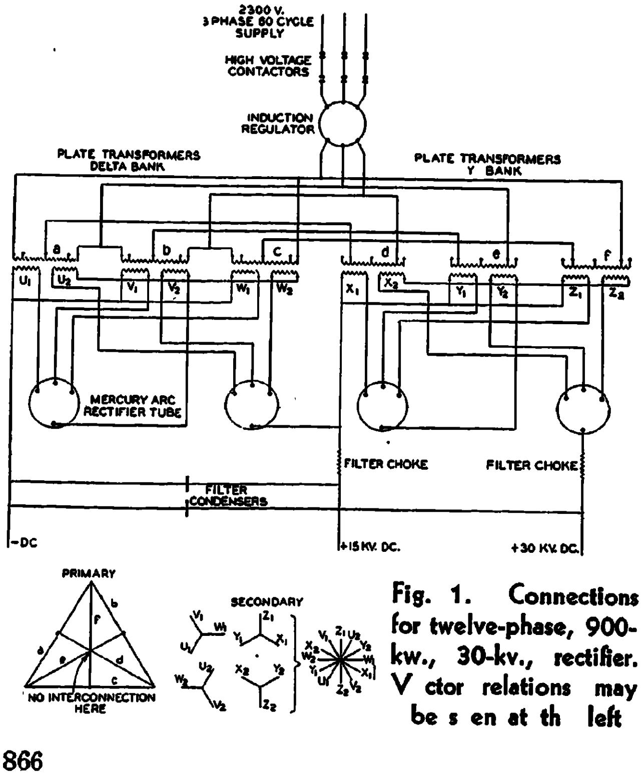

Fig. 1. Connections for twelve-phase, 900-kw., 30-kv., rectifier. Vector relations may be seen at the left

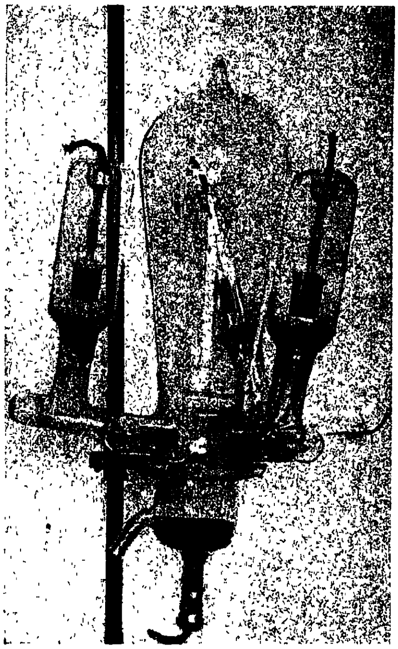

Fig. 2. High voltage mercury-cathode rectifier tube

FILAMENT HEATING GENERATORS

In all but very small telephone transmitters, direct current is required for heating vacuum tube filaments. To meet the requirements of both transmitters, a total of six motor-generators were installed, three normally being assigned to the 980-kc. set and two to the higher frequency outfit, leaving one in reserve. A view of one of these generators is shown in Fig. 4. Each generator is rated conservatively at 1,000 amperes 40 volts d-c., and is driven by a 75-hp. line-start motor operating directly from the 2.3-kv. station supply. To reduce commutator noise to a sufficiently low value so that no filter is required, the design of these generators include special features such as large air gaps, skewed slots and a large number of commutator segments. As an added refinement each unit is mounted on a concrete base and the whole assembly supported on a cork pad to minimize vibration.

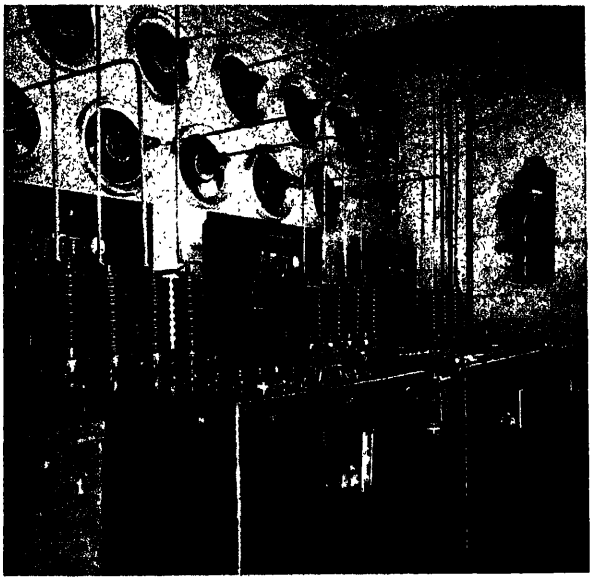

Fig. 3. Tanks housing main rectifier tubes

Interlocks between the tube cooling-water relays and the filament generator field circuit provide low-water protection. A special starting resistance in the field circuit also is interlocked with the filament excitation control which prevents a damaging current rush when voltage first is applied to the tube filaments since these possess only about ten per cent of normal operating resistance when cold.

Besides the six filament-heating motor-generator units, four 10-kw. 3-kv. d-c. generators are employed to furnish plate circuit energy for the smaller intermediate amplifiers and also to provide grid bias voltages. These generators have two 1,500-volt commutators connected in series, and are provided with filters to reduce commutator ripple.

All four generators have one terminal permanently connected to the filament bus or ground circuit. This is possible since the change of polarity necessary when changing from plate to grid service can be accomplished by simply reversing the excitation. To simplify interchange of connections, a special bar and plug board without cables is used. On the rear of this board are mounted vertical and horizontal interconnecting bars to which the transmitter circuits and generator terminals are connected. Any desired combination of connections may be effected simply by plugging through the front of the board to the connecting bars. The dead front construction virtually eliminates live plug danger.

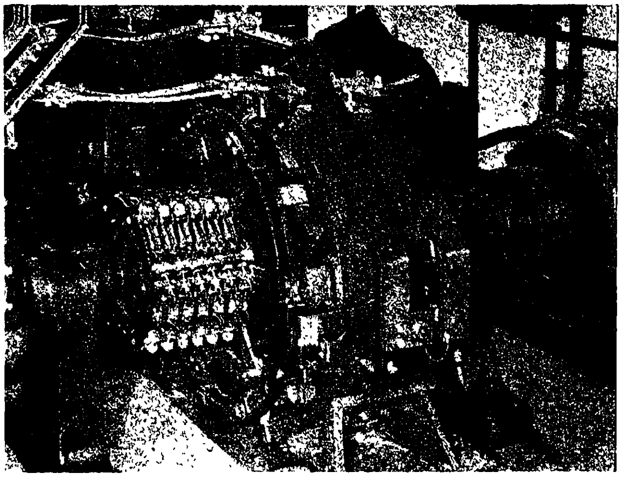

Fig. 4. One of the six 1,000-ampere 40-v lt generators used for tube filament heating purposes

CONTROL EQUIPMENT

The entire control scheme for the power equipment has been arranged in so far as possible so that in the normal course of operation the operator need not leave his position in the main transmitter room. Relays and interlocking mechanisms are provided so that none but the proper sequence of operation is possible. Signal lights adjacent to push-buttons indicate the state of circuit relays and response of contactors being controlled. Suitable meters inform the operator of the operating conditions of all important transmitter power circuits.

All control circuits and meter leads from the outdoor substation to the transmitter building are installed underground to prevent possible high frequency effects. To avoid an otherwise unnecessary 110-volt battery and resulting high voltage drop between the transmitter room and substation, special 400-volt coils were used in the circuit breakers thus permitting their operation from the station "B" battery.

Adequate control of the various intermediate amplifier stages requires the opening and closing under load of 3-kv. d-c. circuits. For this purpose a special 2-ampere contactor was developed having two air breaks in series both equipped with magnetic arc blowouts. The contactor employs a special mechanism to obtain rapid contact travel and wide openings.

OTHER APPARATUS

Besides the major power units which have been described many conventional pieces of equipment are used such as exciters, tube-cooling-water pumps, blowers, battery chargers, and station service transformers for the small power units, lights, and heating. For simplicity of control and convenience in starting, all motors including the 75-hp. units which drive the filament generators, are of the line-start type.

Although one battery will suffice for plate or "B" service, since by the employment of suitable filters it can be charged readily while in use, two filament batteries are advisable because of the difficulty of eliminating hum from heavy-current charging apparatus. Each of these should be capable of handling the entire load for one day. Accordingly, two six-cell, 1,600-ampere-hour storage batteries are furnished for the filament supply of the audio and synchronizing equipment in addition to the previously mentioned 400-volt "B" battery used for plate supply for small tubes. These large batteries also supply essential indicating lamps for the substation circuit breaker control, which require continuous illumination in the event of power failure.

In many broadcasting stations the tube cooling water is cooled in turn by a system of radiators and blowers. At the KDKA station site an opportunity to reduce the investment in cooling equipment was presented by the natural high level of ground water. Accordingly, a small pond was excavated from which sufficient water is obtained for cooling the tube cooling water by means of heat interchangers.

While commercial broadcasting stations as yet do not require equipment as large as that installed in KDKA's new plant, actual construction and use of such apparatus is necessary before the development of commercial high-power stations can be carried out. It is hoped that data can be obtained which will be of value not only in the specialized field of radio engineering but also to electrical science as a whole.

Reactance of Lines With Ground Return

By
J. E. CLEM
Member A.I.E.E.

General Electric Co.,
Schenectady, New York

Charts have been prepared which make possible the fairly accurate determination of the resistance and reactance of the earth return circuit. These values, together with the usual line and ground wire self-inductances, may be inserted in a simple formula to determine the positive or zero-phase-sequence impedance of the complete circuit.

AN ACCURATE knowledge of the zero-phase-sequence impedance of transmission lines is necessary for the successful analysis of current flow during fault conditions. This factor is becoming increasingly important, because the faults which must be considered generally are those involving grounds; the use of the symmetrical-component method greatly simplifies their calculation. The constant increase in size of electric power systems, and in demand for reliability in service, necessitates an application of suitable relays determined largely upon knowledge of current flow during fault conditions. Therefore it is becoming increasingly important that the value of zero-phase-sequence reactance be accurately known. The zero-phase-sequence reactance of transmission lines is the reactance of the three line conductors in parallel with a ground return. The two main problems in the determination of this quantity are the mathematical analysis of the circuit and the determination of the ground return impedance.

Equations have been developed for the impedance of a circuit consisting of any number of line wires in parallel and a return path through ground alone or through ground and any number of ground wires in parallel. The application of these equations, however, is contingent upon a knowledge of the impedance of a single conductor with ground return. The impedance of such a circuit varies with several factors, chief of which is the distribution of the current in the return path below the surface of the earth. While this is largely dependent upon soil conditions, it obviously will vary with the locality and terrain. Hence, field tests have been made to obtain experimental data to use in predicting ground impedance, and to check the theoretical analysis.

From "Reactance of Transmission Lines with Ground Return" (No. 31-64) presented at the A.I.E.E. Middle Eastern District meeting, Pittsburgh, Pa., March 11-13, 1931.

CIRCUIT ANALYSIS

The analysis of the circuit is very simple although it involves such factors as the self-inductance of the earth path and the mutual inductance between a wire and the earth, which usually have been considered as fictitious quantities. By proper manipulation, however, the equations can be made to take on a real and definite form. For the analysis as given here it is assumed that the line wires are transposed so that the same current flows in each of the conductors. It is assumed also that the spread of the current in the earth is such that its mutual effect on all the line conductors or ground wires is the same within the usual horizontal spread of line conductors. Tests show that the error from this source is small.

Consider the circuit shown in Fig. 1. The impedance of such a circuit in this analysis is defined as the ratio of the applied voltage, E_{mn}, to the total current I. The current flows from the generator out along the line wires to the point of fault and back to the generator through the ground and ground wires in parallel. The effect of the current in the ground wire is simulated by a pseudo conductor imbedded in the earth and assumed to have a self-inductance of its own and a mutual reactance with the real conductors of the circuit. The depth of this assumed conductor below the surface of the earth, and its effective diameter, are not of interest for this analysis.

Starting from the generator, the voltage of the circuit is made up of the voltage drop from the generator through the ground to the point of fault and the voltage drop along one of the line conductors from the point of fault back to the generator. The voltage drop in any conductor of a circuit is made up of the voltage drop produced by the current in the conductor and its own self-inductance, and the voltage drop induced in the conductor by the current in other conductors through the mutual inductance. This may be written in the form of an equation; unfortunately, however, such an equation would contain the self-inductance involving the earth. This usually is said to be impossible of separate determination. If this self-inductance is combined with the mutual inductance between the earth and the line wire, or ground wire, reactance quantities are obtained which are real and which can be determined by measurement.

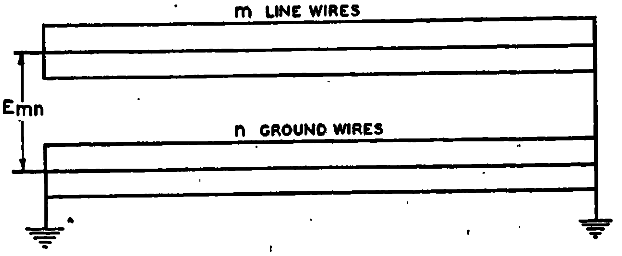

Fig. 1. Fundamental circuit of line wires, ground wires, and ground

of the conductor itself and does not depend in any way upon other conductors in the neighborhood. For mutual inductance another factor of course is required. If the current returns through the other conductor, the voltage drop in the first conductor is $I\ (L - M)$. This quantity $(L - M)$ usually is known as reactance. It can be determined by test or calculations either for a one-way conductor of a circuit alone or for both in series.

By the proper combination of resistances, reactances, and mutual inductances, the following expression for total circuit impedance can be developed:

$$\frac{E_{mn}}{I} = Z_{mn} = Z_{wg} - \frac{I_o}{I} M_{ow} - \frac{m-1}{2m} Z_{ww} \qquad (1)$$

where

$$M_{ow} = \frac{Z_{wg} + Z_{og} - Z_{ow}}{2} \qquad (2)$$

and

E_{mn} = circuit voltage
I = current as indicated by subscripts. Lack of subscript indicates total current
Z = impedance as indicated by subscripts
M = mutual impedance, as indicated by subscripts
m = number of line wires
n = number of ground wires
g = subscript indicating ground
o = subscript indicating ground wire
w = subscript indicating line wire.

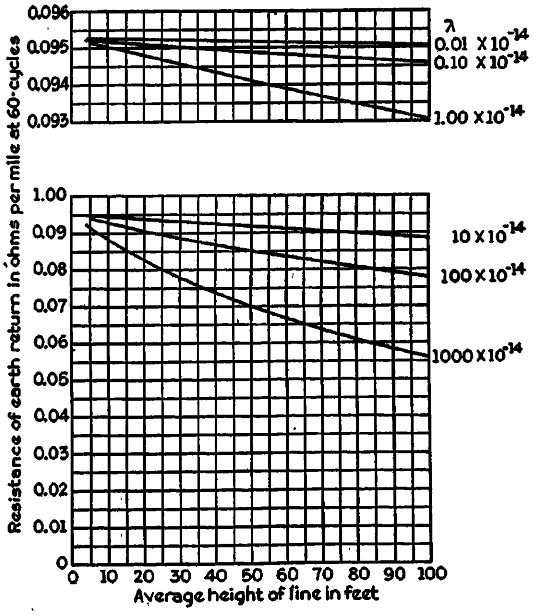

Fig. 2. Resistance of the return path through the earth for different values of earth conductivity λ and height of line

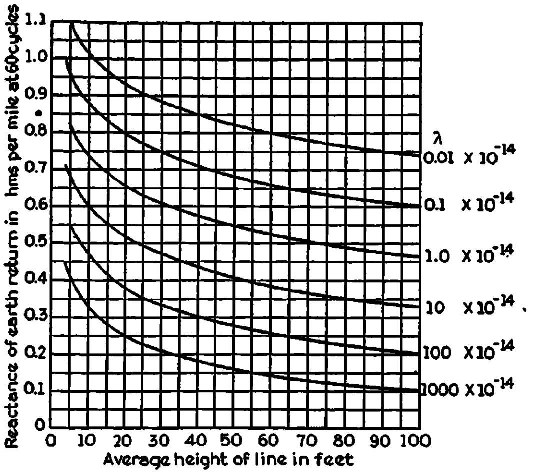

Fig. 3. Reactance of the return path through the earth for different values of earth conductivity λ and height of line

The zero-phase-sequence impedance enters into the calculations of ground fault currents as a quantity which operates on the zero-phase-sequence current. This current is equal and in the same direction in all three line wires and is one-third of the ground fault current. Accordingly the zero-phase-sequence impedance of a transmission line is the quantity obtained by multiplying by three the value of impedance given in equation (1).

The equations for the current in the ground wires may be developed from the fact that the over-all voltage drop from the generator through the ground to the point of fault outside the earth, and along the ground wire to the point of fault must be equal. The resulting equation is

$$\frac{I_o}{I} = \frac{M_{ow}}{Z_{og} - \frac{n-1}{2n} Z_{oo}} \qquad (3)$$

To check the analysis field tests were made on four power systems facilitated by the use of a test wire parallel to the transmission circuit. These tests were made both with and without a ground wire and definitely indicate that the analysis is correct within a few per cent in all cases.

GROUND RETURN IMPEDANCE

The successful application of the mathematical analysis depends upon a predetermination of the ground return impedance. The main problem in the calculation of ground fault current and the division of the return current between the ground wires and ground is the predetermination of the impedance of the fundamental circuit consisting of the conductor with ground return.

For many years it was customary to consider the earth as a perfectly conducting plane. All the reactance was assigned to the conductor and the corresponding distance to the "neutral plane" was calculated. This gave effective conductor heights up to several thousand feet and a wide variation was found, so that no good method of predicting the impedance of the circuit could be built up.

The calculation of the impedance of the fundamental circuit made up of a conductor with ground return requires a study of the distribution of the current in the ground. A solution to this problem has been given by Carson in the *Bell System Technical Journal,* October 1926. With some modification the expression developed by Carson states that the total impedance of the circuit equals the resistance of the conductor plus the reactance of the conductor plus the impedance of the ground return. The reactance of the conductor is calculated as if the return conductor were below the surface of the ground a distance equal to the height of the conductor. In other words, it is the one-way reactance of the conductor with image return.

The impedance of the earth Z_g in the solution worked out by Carson depends upon the conductivity of the earth, the distance from a conductor to its image, and the frequency. From these variables and an additional

factor dependent upon the configuration of the conductors, two values may be obtained from previously prepared tables which give directly the value of the impedance of the earth. A sufficiently accurate result for ordinary purposes, however, may be obtained from the curves of Figs. 2 and 3, based on Carson's formula with some simplification.

To apply this method it is necessary to have some idea of the values of the conductivity of the earth, since that is the final variable. Test values of earth conductivity are given in Table I. They apply to specific tests, but may be used to estimate the value of earth conductivity for other regions. The striking thing about this data is the wide variation in earth conductivity for a relatively small variation in ohms per mile impedance.

Fortunately, it is not necessary to know the value of earth conductivity with any great degree of accuracy to determine within a reasonable degree of accuracy the impedance of a transmission line with earth return. An error of 1,000 per cent, ten to one, in the value of earth conductivity will give about 30 per cent error in the earth reactance, which reduces to about 13 per cent error in the reactance of the circuit of conductor with ground return. The relative error dwindles further when the line reactance is in series with transformer and generator reactance.

In solving any particular problem it is necessary only to select the most probable values of earth conductivity for the line in question and then read off the unit values for ground resistance and reactance for the proper value of average height of line. These values in the proper relation to the test or calculated values of conductor impedance then can be inserted in equation (1) to give the impedance of the total circuit. The value of impedance for the various conductor groupings can, of course, be obtained by the customary method.

For values of earth conductivity at frequencies other than 60 cycles, the curves of Figs. 2 and 3 can be applied using an effective height equal to the square-root of the ratio of the actual frequency to 60 cycles. The values read from the curves also must be changed from 60 cycles to the actual frequency by direct proportion.

Circle Diagrams for Short Lines

When once constructed, circle diagrams furnish the means by which many phases of transmission-line performance can be checked quite readily. A method is given here by which the center loci are determined for a large number of short-lines where capacitance may be neglected.

By
T. D. OWENS
Member A. I. E. E.

Case School of Applied Science, Cleveland, Ohio

CIRCLE DIAGRAMS for transmission lines serve two general purposes: they furnish a check on long and laborious calculations, and in addition present a visual picture of the problem which mathematical solutions fail to give. Furthermore, when once constructed, such diagrams yield solutions for a large number of possible operating conditions with very little added work. For problems such as the determination of synchronous condenser capacity required for constant-voltage operation and stability, this feature is extremely valuable.

In the following discussion the visual conception and interpretation of the circle diagram is extended to include in addition to the usual factors involved, the effects of conductor size, spacing, and length. The method is particularly advantageous for use with short lines wherein capacitance is small. While this method can be used also for long lines, it loses its directness and generality in such cases, and much additional calculation becomes necessary. The treatment therefore will be restricted to the case of negligible capacitance.

Symbols used throughout the entire discussion are shown in Table I.

Table I—Symbols

P_R = in phase receiver power per phase in kw.
Q_R = quadrature receiver power per phase in kva.
E_R = receiver voltage to neutral in kv.
E_S = sending voltage to neutral in kv.
r = conductor resistance per mi. in ohms.
x = conductor reactance per mi. in ohms.
z = conductor impedance per mi. in ohms.
s = length of one conductor in mi.
f = frequency in cycles per sec.
D = conductor spacing in in.
a = conductor area in cir. mils.
ρ = resistance of conductor in ohms per mil-ft.

Written specially for ELECTRICAL ENGINEERING. *Not Published in pamphlet form.*

The well-known general equation for the circle diagram is as follows:

$$\left[\frac{P_R}{E_R^2} + \frac{r}{z^2 s} 10^3\right]^2 + \left[\frac{Q_R}{E_R^2} + \frac{x}{z^2 s} 10^3\right]^2 = \frac{E_S^2}{E_R^2 z^2 s^2} 10^6 \qquad (1)$$

This equation represents, for a specific line, a set of concentric circles the radii of which are dependent upon the ratio of sending to receiving voltage. The center of all the circles does not coincide with the origin but may be placed in the second quadrant at a point such as c in Fig. 1. The coordinates, l and m, may be seen from equation (1) to be:

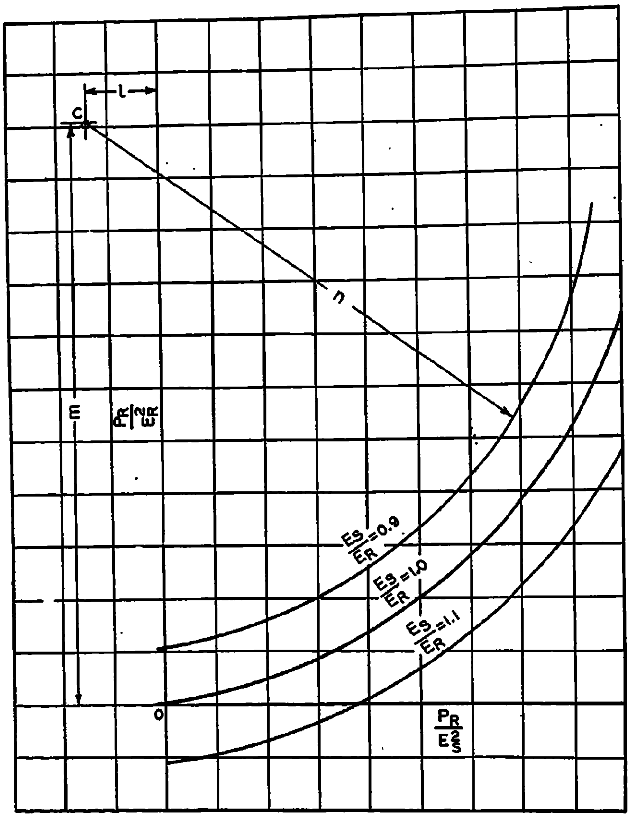

Fig. 1. General circle diagram for transmission lin neglecting capacitance, where l and m are as shown in equations (2) and (3)

$$l = \frac{r}{z^2 s} 10^3 \qquad (2)$$

and

$$m = \frac{x}{z^2 s} 10^3 \qquad (3)$$

If the circle radius be denoted by n, then

$$n = \frac{E_S 10^3}{E_R z s} \qquad (4)$$

From equations (2), (3), and (4) may be seen that the coordinates of the center c of the family of circles and their radii are dependent upon the values of r, x, and s. These constants in turn are functions of the conductor size, spacing, and length. The usual formulas for resistance and reactance per mile may be written thus:

$$r = \frac{5280 \rho}{a} \text{ ohms per mi.} \qquad (5)$$

$$x = 2 \pi f \left(741.1 \log_{10} \frac{2 D 10^3}{\sqrt{a}} + 80.47\right) 10^{-6}$$

$$= 0.00466 f \log_{10} \frac{2570 D}{\sqrt{a}} \text{ ohms per mi.} \qquad (6)$$

The constants l, m, and n now may be written in terms of a, s, and D.

$$l = \frac{5280 \rho 10^3}{a s \left[\left(5280 \frac{\rho}{a}\right)^2 + \left(0.00466 f \log_{10} \frac{2750 D}{\sqrt{a}}\right)^2\right]} \qquad (7)$$

$$m = \frac{\left(0.00466 f \log_{10} \frac{2570 D}{\sqrt{a}}\right) 10^3}{s \left[\left(5280 \frac{\rho}{a}\right)^2 + \left(0.00466 f \log_{10} \frac{2750 D}{\sqrt{a}}\right)^2\right]} \qquad (8)$$

$$n = \frac{E_S 10^3}{E_R s \sqrt{\left(5280 \frac{\rho}{a}\right)^2 + \left(0.00466 f \log_{10} \frac{2750 D}{\sqrt{a}}\right)^2}} \qquad (9)$$

To determine how the locus of point c is affected by any one of the three variables a, s, or D, let two remain fixed while the third is allowed to vary. In Fig. 2 the distance s is arbitrarily taken as 10 mi. and the frequency f as 60 cycles. By taking a series of fixed values of D and plotting the locus due to variation in conductor area for each, a set of curves is found of which $F b$ is an example.

Similarly by taking a series of fixed conductor areas a and allowing the spacing D to vary, another set of loci is obtained as illustrated by $G H$. Thus for this particular line of 10-mi. length the center may be located for any spacing and conductor area if a sufficient number of curves are plotted. While the center is varying in position due to a and D, the radius n also is affected. From the geometry of the figure

$$o c = \sqrt{l^2 + m^2} - = \frac{10^3}{z s} \qquad (10)$$

From the ratio of n to $o c$ in equations (4) and (10)

$$n = \frac{E_S}{E_R} o c \qquad (11)$$

The length of the corresponding radius for any position of c is therefore equal to the distance from c to o multiplied by the voltage ratio.

With the construction as outlined the diagram is general in regard to voltage. Once E_R is chosen the scales on the two coordinate axes become directly proportional to the quadrature and in phase receiver power. E_S is determined of course by the voltage ratio selected.

To determine how the diagram can be adapted for values of s other than that for which the diagram is drawn, (10 mi. in this case), it is necessary only to examine equations (2), (3), and (4). These equations show that for a given set of values of the constants r and x, or a and D, l, m, and n vary inversely as s. Therefore if a diagram for a line of 20 mi. is desired it is necessary only to divide the distances l, m, and n by two. An equivalent process which avoids the construction of a new set of curves is to divide the scales on the axes by two. In general then for any length s' the scale readings on the axes should be multiplied by $10/s'$.

As an example of the use of the chart, consider a transmission line with the following data:

Line voltage = 110 kv.
Spacing = 15 ft.
Conductor size = 350,000 cir. mils
Length = 20 mi.

Suppose that the corrective kva. at no-load is to be determined assuming a voltage ratio of 1.1. The circle drawn in Fig. 2 represents this case. The intercept on the horizontal axis is 12.5 units lagging. Then for a length of 20 mi.,

$$\frac{Q_R}{E_R^2} = 12.5 \times \frac{10}{20}$$

$$Q_R = 12.5 \times \frac{10}{20} \times \left(\frac{110}{\sqrt{3}}\right)^2$$

$$= 25{,}200 \text{ kva. per phase}$$

Other applications of the chart to practical every day problems can be shown to be equally simple.

Simplicity and Economy of Oil Filled Cable

Oil filled cable has been developed for successful use at the highest operating voltages. Attention now is being focused on the economies of oil filled cable systems and on means of simplifying their installation, with a resulting freedom from failure due to mechanical causes. The three articles which follow the short introduction below, discuss these factors.

DURING the past four years large installations of 132-kv. oil-filled cable and others of lower voltage rating have been placed in service. The electrical performance of all of these installations has been outstanding and each successive installation has represented an improvement in the way of simplification and economy. For ratings above 70 kv., oil filled cable is superior to the solid type in every respect; and it appears that the rating of oil filled cable can be extended to 220 kv. when required.

The term "oil filled" as applied to impregnated paper cable is understood ordinarily to indicate a cable in which the impregnating compound is of such viscosity as to be fluid at all operating temperatures. Such a cable must be constructed to permit free passage of the oil longitudinally and radially, and must be connected to a suitable oil supply. To keep the hydrostatic head of the oil from becoming excessive, oil stop joints must be inserted in the cable.

When properly constructed, such a cable system presents a number of advantages over solid cable. The free ebb and flow of the saturant removes the danger of heat expansion and consequent formation of bubbles or voids in the insulation under repeated load and temperature cycles. The deterioration of insulation is no longer an important factor to contend with, higher operating temperatures may be used, the voltage and current ratings may be increased considerably, and the thickness of insulation may be reduced. For a given size of duct more power can be carried. The dielectric loss of oil filled cable is quite low and there have been no indications of an increase in loss with time and service. Flaws and defects in the lead sheath result merely in a slow leakage of oil, which can be located and repaired at any convenient time. In solid cable the first warning of such defects is electrical service failure caused by the entrance of moisture and air.

In addition to improved characteristics of oil filled cable, the cable accessories have been developed so that the installation and operation of cable systems has been considerably simplified and the cost reduced. This reduction in the difficulty of installation is of considerable importance and should do much to make the use of oil filled cable at the higher voltages widespread.

Economics of High Voltage Cable

Careful studies have been made of the economics of the various types of cables for application in the Chicago district. The conclusions resulting from these studies are surprisingly definite, and indicate the trends in high voltage cable practise, especially as relating to the oil filled type.

Company, Chicago

OIL FILLED CABLE for operation at 132 kv., placed in service in Chicago in 1927, was designed in 1925 to have the largest carrying capacity commercially feasible for that voltage in the state of the art as it then existed. In the ensuing years improved oil and new designs of oil supply tanks simplified the design of the terminal to the extent indicated in Fig. 1; shipping the cable full of oil and the development of methods of making joints on the cable full of oil reduced the factory cost of the cable and the cost of installation in the field; successful operating experience on lower voltage cables with devices and methods for eliminating sheath losses had removed the limitation on the economical size of the conductor. As a result

---

From "Economics of High Voltage Cable" (No. 31-108) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

of these developments, a second line was installed in 1930 in the same conduit as the first line, having a carrying capacity 75 per cent greater but at 20 per cent less cost. These two cables are illustrated in Fig. 3.

While the design of the line installed in 1930 was under consideration a number of other questions regarding underground transmission in the Chicago district arose, as follows:

1. What is the maximum economical size of single-conductor cable for connection between the 12-kv. bus and a 60,000-kva. transformer bank?

2. Is there any economy in the use of oil filled cable for 66-kv. service?

3. What is the maximum load per line that can be carried on 132-kv. oil-filled cable in 4-inch ducts?

4. Can 220-kv. cable be obtained if desired, and what will be the approximate cost?

It therefore was decided to review for Chicago conditions the entire subject of high voltage cable so that in addition to answering these questions, it would be possible to determine what changes in existing practise were indicated by recent developments.

Preliminary calculations on typical cables in use in Chicago indicated wide differences in the relative amounts of the various items entering into the initial cost and annual charges; and further, that the cable with the lowest total annual charges might not always be the one with the lowest first cost. Accordingly the plan was adopted of calculating curves showing, for Chicago conditions, the variations of the initial cost and annual charges for the entire range of commercial sizes so as to determine the most economical transmission voltage and type of cables for various Chicago conditions. These curves are given in Figs. 2 and 4. The investment costs include labor and supervision, conduits and manholes, joints and accessories, and cable. The annual charges include the cost of failures, maintenance, insulation loss, sheath loss, copper loss, depreciation, and interest and taxes.

The calculations were confined to cables for the transmission voltages in use except that, with some assistance from the manufacturers, 220-kv. cable was added. In determining the size, type or voltage of transmission cable, due consideration should be given to the effect on the entire system of generation, transmission and distribution of which the cable is to be a part.

As the *relative* initial and annual costs of various types were desired, it was considered more important that the unit cost figures be the same for all calculations than that they should fit any particular case. Accordingly the same physical constants, unit costs, and conditions were used throughout the calculations. Among the factors investigated which affect initial and annual costs were elimination of sheath losses on single-conductor cables, dielectric loss, maximum permissible operating temperature, load factor, and improvement in power factor of the system due to the charging current of the cables.

A study of the curves leads to the following conclusions:

1. The most economical cable for a given set of conditions should be determined by considering the total annual charges, rather than the first cost.

2. The inclusion of the terminal charges makes but slight difference in the *relative* costs of the various types and voltages of cable. This indicates that the relative costs of the various types and voltages of cable would be altered only slightly by assumptions somewhat different from those used in the calculations.

3. For every load there is one type of cable and one transmission voltage which is more economical than any other combination.

4. For a given type and voltage of cable, maximum economy generally is found with larger cables than are in ordinary use.

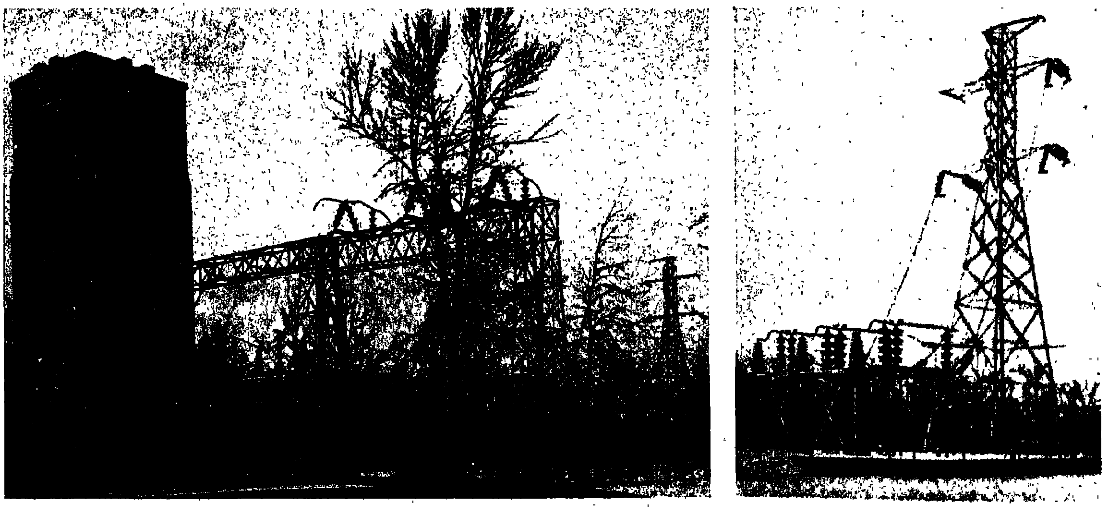

Fig. 1. The electrically heated terminal and oil reservoir tower of the 132-kv. cable line installed in 1927 is shown on the left, while on the right is the outdoor terminal of the 132-kv. line installed in 1930

5. Three-conductor cables are the most economical for loads up to about 50,000 kva. For the upper half of this range, three-conductor, 66-kv., oil-filled cable is the most attractive, but requires larger ducts than are now in ordinary use.

6. For loads above 50,000 kva. per line, single-conductor cable should be used.

7. The elimination of sheath losses by the use of insulating joints and bonding transformers permits the efficient use of large single-conductor cables between the 12-kv. bus and transformers for high voltage lines. The reduction in annual charges is indicated in Fig. 5.

8. For cable to operate at 66 kv., a moderate reduction in the cost of oil-filled single-conductor cable and in the cost of the joints and accessories would bring the oil filled type in competition on a cost basis with cable of the ordinary type.

9. For loads of the order of 100,000 kva. per line, oil-filled, 66-kv., single-conductor cable is preferable to the ordinary type when the overall diameter of cable is limited by the size of the ducts in existing conduits.

10. There is no economy in using 132 kv. for tie-lines between stations in Chicago until the required carrying capacity exceeds 125,000 kva. per line. In so far as carrying capacity of the cable is concerned, there is no occasion for increasing the transmission voltage above 132 kv. until the required capacity per line exceeds 250,000 kva.

11. The cost of cable for 132 kv. and higher voltages will probably limit its use to underground extensions, within large cities, of long overhead transmission lines from distant stations.

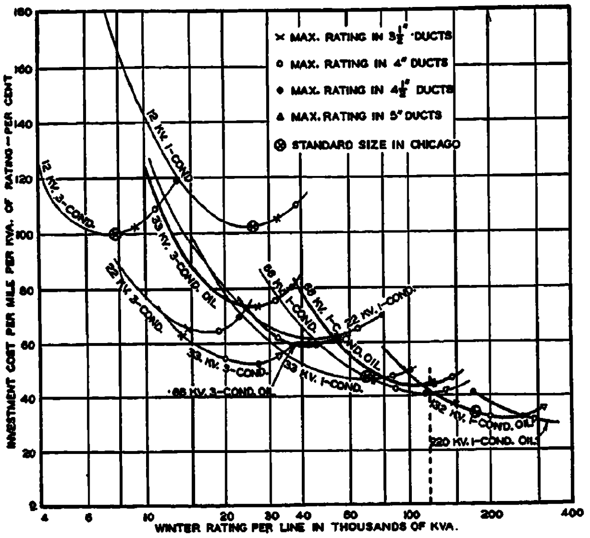

Fig. 2. Relative investment costs of underground lines, excluding terminals

One cable per duct; 6 to 10 identical cables per conduit. Minimum cost for 12-kv. three-conductor cable assumed as 100 per cent

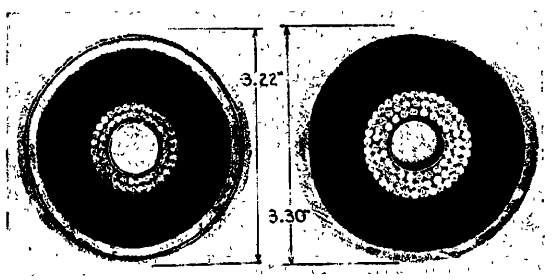

Fig. 3. The 132-kv. oil-filled cable for the 103,000-kva. line installed in 1927 (left) and for the 188,000-kva. line installed in 1930 (right)

12. As the fixed charges are about three-fourths of the total annual charges, the best way to reduce annual charges is to reduce first cost.

In determining the best transmission cable for a given purpose, the decision should not be restricted by preconceived ideas of the relative importance of transmission voltage, dielectric loss, skin effect, maximum efficiency of insulation, Kelvin's law, the size or number of ducts in the conduit, or other physical laws and constants; but, by taking all such subjects into consideration, the type, size and voltage of cable and conduit details should be determined so as to secure the lowest annual charges for the given conditions.

COMPARISON OF INSULATION

At current prices and with the thicknesses of insulation now specified by the manufacturers for the various operating voltages, 66-kv., three-conductor, oil-filled

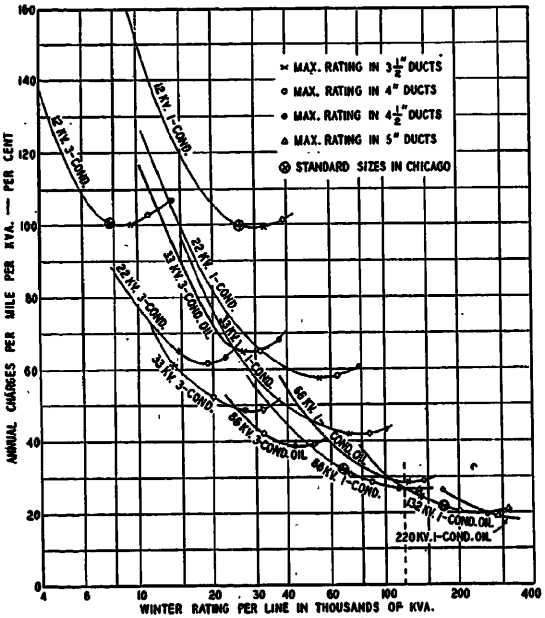

Fig. 4. Relative annual charges for underground lines, excluding terminals

Annual load factors: 12 to 33 kv., 45 per cent; 66 to 220 kv., 60 per cent. Minimum charges for 12-kv. three-conductor cable assumed as 100 per cent

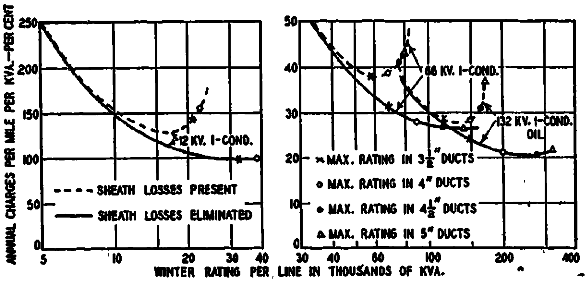

Fig. 5. Effect of sheath losses on annual charges for single-conductor cables. Load factors and vertical scale same as for Fig. 4

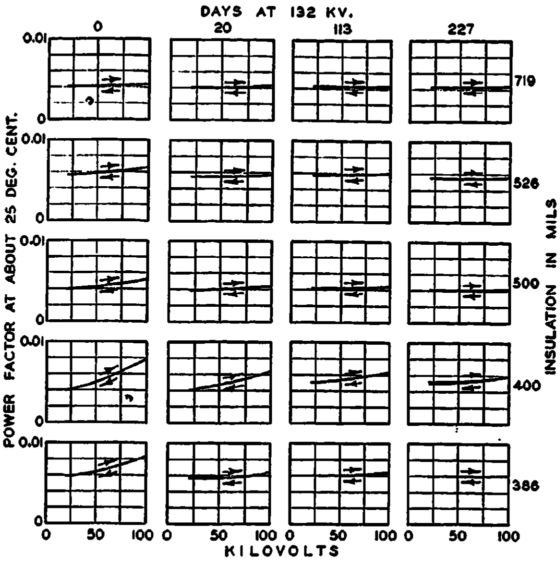

Fig. 6. Typical power-factor curves for 132-kv. oil-filled cable subjected to daily load cycles with maximum copper temperature of about 70 deg. cent.

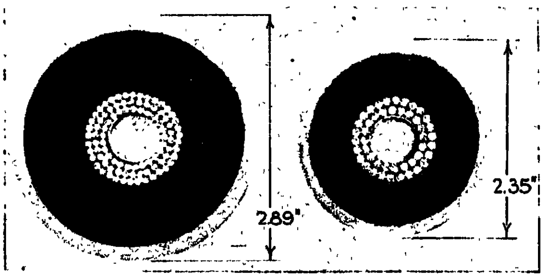

Fig. 7. 600,000-cir. mil commercial cable on the left and 475,000-cir. mil experimental cable on the right, both f r same ampere capacity at 132 kv.

cable is the most economical type for loads ranging from about 25,000 to 48,000 kva. For loads ranging from about 48,000 kva. to 120,000 kva. per line, single-conductor cable with the ordinary type of insulation is the most economical. A reduction of about 10 or 15 per cent in the cost of oil filled cable and a reduction of about 30 per cent in the cost of the accessories for this type of cable would place the oil filled type in price competition with the ordinary type over this range of loads. Further reductions in the price of oil filled cable and accessories will be necessary in order to place it in competition with the ordinary type of insulation for lower voltage cable.

As indicated by Fig. 6, investigations on oil filled cable with reduced thickness of insulation, operated at 132 kv., show no adverse changes in the insulation as determined by power-factor measurements after operating for eight months with daily load cycles. Apparently the thickness of insulation now used for this voltage could be reduced safely. Present information indicates that the thickness of oil filled insulation for 132 kv. may be determined by the transient voltage disturbances rather than by the normal stresses due to the operating voltage.

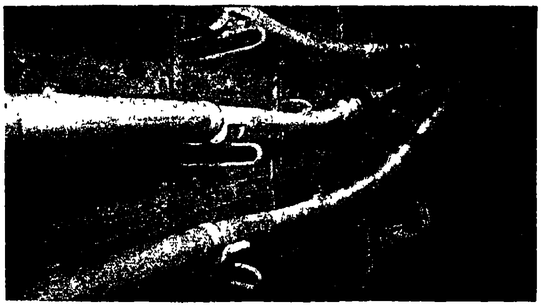

Fig. 8. Installation of equipment for eliminating sheath losses on 132-kv., 188,000-kva. cable

Left—Normal cable joints before fireproofing
Center right—Insulating joints in cable sheaths
Lower right—Bonding transformer for reducing sheath voltages

A reduction in the present thickness of the insulation of oil filled cable appears warranted by the remarkable operating record of the installations in this country, the record being that there have been over 250 mile-years of operation of the cable without any failures of the insulation. A similar record has been made by one make of 66-kv. cable with the ordinary type of insulation. This should indicate also the reasonableness of reduction of the ordinary type of insulation for 66-kv. cable.

Whether the oil filled type will displace the ordinary type at 66 kv. and lower voltages, or the ordinary type compete with the oil filled type at 132 kv., depends on the relative rates of improvement and reductions in cost of the two types of insulation with unrestricted competition.

Present indications are that the maximum temperature limit for high voltage cable may be imposed by the limitations of the lead sheath rather than by the properties of the insulation. It appears possible that the advancements in the art in the next ten or fifteen years will permit the insulation thickness for 132-kv. cable to be reduced from 719 mils to 500 mils, and the maximum temperature to be increased from 65 deg. cent. to 80 deg. cent. Fig. 7 shows the extent to which the diameter of the cable would be reduced by these changes.

When all the research investigations now in progress or contemplated by the utilities, universities and manufacturers have been brought to a successful conclusion the following results should have been attained:

1. Cables of all types and voltages will be operated at a maximum temperature of 85 to 90 deg. cent. without fear of deterioration.

2. The expensive oil reservoirs and accessories on oil filled cable will be eliminated due to:
    - (a) Increase in the elastic limit of the cable sheath.
    - (b) Reduction in the thermal coefficient of expansion of the oil.
    - (c) Making the insulation somewhat compressible under moderate pressures existing with the lead sheath.

3. An installation of oil filled cable will be no more complicated than a present-day installation of ordinary type of cabl .

4. Cable of subnormal quality will be eliminated by tests at the factory.

5. The initial cost per kva. of 66-kv. cable completely installed will be from 30 to 40 per cent below the present cost of the ordinary type.

6. Cable failures due to all causes will not exceed one per 100 miles per year.

If all of these results should be achieved within the next fifteen years, it would be no more startling than a statement of the present day state of the art would have appeared fifteen years ago. To keep pace with the advancements being made by the manufacturers, the utilities must improve their standards of design and workmanship.

Layout of Oil Filled Cable Systems

Problems concerned with the supply of oil largely govern the layout of oil filled cable installations. Consideration must be given not only to the characteristics of the oil itself, but also to certain properties of the cable and duct structure governing the volume and pressure of oil required.

REQUIREMENTS which must be met in order that the operation of oil filled cables be successful include the following:

1. A stable non-freezing oil of superior electrical properties. This oil should have predetermined viscosity characteristics that give assurance against void formation in the cable cross-section and excessive loss of pressure along the feed channels.

2. The wood pulp paper shall be of high quality, compactly and uniformly applied, and of predetermined density.

3. All impurities such as moisture and gas, both free and in solution, shall be removed from the cable during manufacture, and from all accessories and fittings during installation.

4. Positive pressure shall be maintained at all times inside the entire length of cable and other parts of the oil system.

5. The oil pressure should never exceed the safe working limits determined by the mechanical strength of cable sheath and accessories.

In laying out the most effective and economical installation of oil filled cable, primary consideration must be given to the problem of oil supply including the rate of expulsion and absorption of oil by the cable, oil pressure drop along the feed channels, total expulsion or absorption of oil between the extreme limits of no-load winter temperature and full-load summer temperature, and the characteristics of available reservoirs to take care of volumetric changes in the oil caused by these fluctuations in temperature.

Typical oil demand curves of the cable, upon the sudden dropping of load, are shown in Fig. 9. Cable 1 has an inside diameter of core of 0.5 in. and a copper conductor cross-section of 600,000 cir. mils, with an over-all diameter of 2.84 in.; while cable 2 has an inside diameter of 0.5 in., a copper cross-section of 475,000 cir. mils, and an over-all diameter of 2.3 in. The measurements were made for two different oil pressures maintained in the hollow core as shown. Measurements of oil demand when the same load is applied also were taken, but the two sets of measurements coincided so closely that the latter data will not be given. The fact that these measurements coincided indicates that voids were not formed when the load was dropped. Also, if voids had been formed, the demand measurements with low oil pressure would be less than with the high pressure. As indicated in Fig. 9, these measurements were identical. Also, the theoretically calculated curves of Fig. 9, based on the assumption that no voids were formed, are in almost exact agreement with the test measurements.

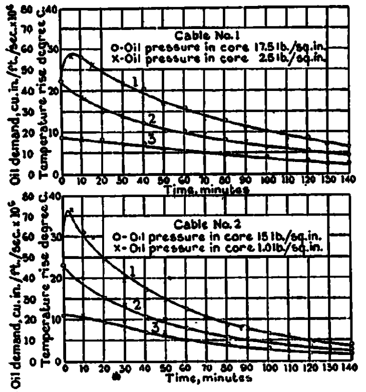

Fig. 9. Curves of (1) oil demand, (2) copper temperature rise, and (3) sheath temperature rise, after dropping load. Calculations are shown by curves, and test results by points

Oil pressure drop along feed channels and piping during periods of oil flow can be calculated with acceptable accuracy only when the inner surface is smooth and cylindrical, and the rate of flow is less than turbulent. The friction factor can be calculated to allow for surfaces which are not smooth, when a spiraled supporting member is used, but it is usually necessary to confirm such calculations by test.

The total oil required is a direct function of cable length and the two extreme limits of temperature met with in service. For underground cable these limits are usually assumed as 0 deg. cent. no-load winter temperature, and 70 deg. or 75 deg. cent. full-load summer temperature. The total oil requirements can be

---

From "Characteristics of Oil Filled Cable" (No. 31-97) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

calculated on this basis. Usually 40 per cent over the theoretical requirement is added to the reservoir capacity as an emergency surplus and to safeguard against possible discrepancies in calculations or wrong adjustment of reservoir content. For typical single-conductor and three-conductor cable, the total oil requirement based on the theoretical value plus 40 per cent varies from 0.5 gal. to 2.0 gal. per 100 ft. of cable.

The types of oil reservoirs which have proved most useful and desirable for oil filled cable installation are the gravity-feed reservoir and the balanced-pressure reservoir. These reservoirs are identical in design and construction with the exception that the outer rigid enclosing tank of the gravity-feed reservoir is open to the atmosphere through a breather, maintaining practically constant atmospheric pressure on the oil. On the other hand the balance-pressure reservoir has a sealed gas-tight outer tank, maintained under variable gas pressure. Both types follow the established principle of segregating and sealing-off the cable oil system against exposure to gas or other impurities. The gravity-feed reservoir must be elevated of course above its surroundings and in locations where elevation is undesirable or impractical, the balanced-pressure type may be used. These are adjustable so that units at different elevations can be made to work together.

In addition to the four factors discussed above, dealing with oil supply, there are a number of other characteristics which must be known before an oil filled cable installation can be laid out properly. One of these is the steady and transient thermal characteristics of the cable and surrounding duct structure, curves of which are given in Fig. 10 for cable 1 previously described. If full load on the cable had been dropped, the maximum rate of oil supply would have been greater than when dropping half load as in Fig. 10; however, the maximum pressure drop would have been less. This is accounted for by the difference in oil viscosity.

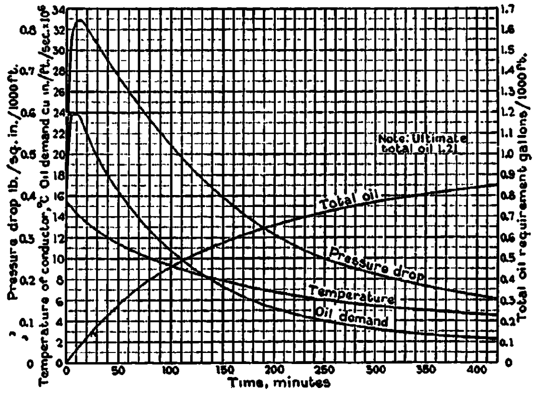

Fig. 10. Effect of dropping half load from six cables in duct bank. Based on winter conditions of 0 deg. cent. ambient earth

All of the necessary factors for cable 1 have been described and we are now in a position to lay out an actual installation. The contour of the duct run, spacing between manholes, dimensions of manholes and other practical considerations will determine the best and most economical layout. Pressure drop along the core, minimum oil pressure at high point, maximum pressure at low point and other factors will determine the location of oil stop joints and the type of oil feed for each section between stop joints. Two typical sections will be selected for discussion.

First, assume a duct contour as shown in Fig. 11, with stop joints at position 0 ft. and 3,000 ft. The sheath of cable 1 has no reinforcement and steady oil pressure at the lowest point (1,500 ft.) must not exceed 15 lb. per sq. in. Also it is desirable to avoid either a steady or transient oil pressure lower than atmospheric at any point in the oil feed system, consisting of reservoir cells, piping, stop joints and cable core. From the previous work it is known that the total rated oil capacity of the reservoir units for this length of cable is 25 gal.

Balanced-pressure reservoir feed obviously is out of the question, since the hydrostatic pressure from position 0 to 1,500 ft. is already the full allowable 15 lb. If gravity-feed units are placed at position 0 ft. and at an elevation slightly above the stop joint, the minimum pressure in the cable core when full and half-load are dropped in the winter-time is shown by curves 1 and 3. Both of these curves intersect the cable contour, and the oil system beyond these points of intersection would be at a pressure below atmospheric for several minutes. If the gravity-feed reservoirs are raised to sufficient height as shown by curve 5, this condition could be avoided; but this solution is not desirable since instead of mounting the reservoir units directly in the manhole, it would mean an expensive reservoir housing above ground level. Also, safe working pressure of 15 lb.

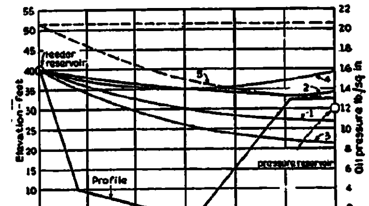

Fig. 11. Typical section of cable with feeder and pressure reservoirs

Feeder reservoir rated 25 gal.
Pressure reservoir rated 3 gal. oil, 15 gal. gas.

Curve 1—Pressure curve while full load is dropped in winter, feeder reservoir only

Curve 2—Same condition as Curve 1 with feeder-pressure reservoir combination

Curve 3—Pressure curve when half load is dropped in winter, feeder reservoir only

Curve 4—Same as Curve 3, with feeder-pressure reservoir combination

Curve 5—Same as Curve 3, shows height to which feeder reservoir must be raised to avoid vacuum at the far end under all conditions

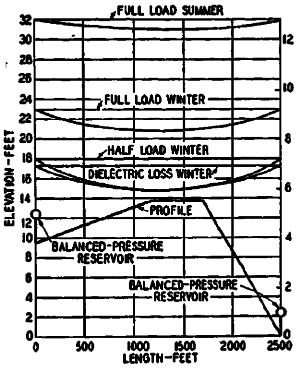

Fig. 12. Typical section of cable with balanced pressure reservoir

Oil volume—
10 gal. each reservoir
Gas volume—
41.6 gal. upper reservoir
54.0 gal. lower reservoir

would be exceeded at the lowest point of cable contour.

The real solution is to leave the gravity-feed units at stop-joint level and connect a small pressure reservoir at the low end of the section. This pressure reservoir functions only during transient periods of temperature change and during these periods assists in maintaining cable core pressure within prescribed limits. Curves 2 and 4 with pressure reservoir connected show the improvement in pressure characteristics accomplished by the addition of this small unit.

On level ground or where the profile of a given section is such that the feeder-pressure combination just described cannot be used without resorting to expensive mounting of reservoirs above ground level, the so-called balanced-pressure feed proves very convenient and economical. Fig. 12 shows a 2,500 ft. section of cable line having a contour that can be taken care of most conveniently by balanced-pressure feed. In all other respects the assumptions are the same as outlined for Fig. 11. The total rated oil capacity is found to be 20 gal. This should be divided equally, one 10-gal. balanced-pressure unit being placed at each end, the relative elevations of these reservoirs being as shown in Fig. 12.

The gas capacity of these units and their initial volumetric and pressure settings are so selected that each reservoir takes care of exactly half of the cable section. Also, the pressure at the highest point in the oil system must never drop below 1 lb. above atmospheric, and the pressure at the lowest point must never exceed 15 lb.

The pressure along the cable core under various limiting conditions is also shown. It will be noted that dropping either half-load, or merely dielectric loss in the winter and full-load pressure in the summer represent the extreme limiting conditions.

There are many factors that determine the best and most economical system of oil feed and general layout of oil filled cable installations. The best system might vary anywhere from a stop joint and reservoir in every manhole, where very rugged contour is encountered, to complete exclusion of stop joints on level ground. Generally speaking, the use of stop joints should be reduced to a minimum. Stop joints should be used merely for segregation, since the advantages gained are nullified by the additional expense and the limited amount of reservoir oil available for emergency use in case of accidental leakage.

Accessories for Oil Filled Cable

The development of more satisfactory cable joints, terminals, and reservoirs has greatly simplified the installation of oil filled cable and increased the reliability against mechanical failures.

By
R. W. ATKINSON
Fellow A. I. E. E.

D. M. SIMMONS
Fellow A. I. E. E.

Both of
General Cable Corp.,
New York, N. Y.

PARALLEL with the development of an oil filled cable for high voltage use, notable progress has been made in securing the simplicity of installation afforded by the ordinary type of cable. This factor is of considerable importance to the general use of oil filled cable for high voltages, as the difficulty of installing the earlier system handicapped its use considerably. A background of very successful practical experience now has been secured with the newer and simpler types of joints, terminals, and accessories.

The fundamental features about which this system has been built are:

1. Shipment of cable filled with oil, and without field evacuation and reimpregnation.

2. Stop joints of moderate size and cost, and a rapid and reliable technique of installation, making practicable oil feed lengths as short as desired.

3. Reliable oil feed system, including compact designs of expansion oil reservoir with oil volume indicator, and an automatic signal system designed to give to oil filled cable the same superiority over solid type in freedom from service failures due to most types of mechanical causes that it now enjoys with respect to electrical trouble.

4. For multiple-conductor cable, provision of oil channels in the filler spaces, making the system equally applicable to single-conductor and three-conductor cables.

From "Oil Filled Cable and Accessories" (No. 31-100) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

The cross-section of single-conductor 132-kv. cable in Fig. 13 shows the oil channel which is provided in the center of the conductor and also a number of longitudinal slots in the inner surface of the sheath which are sometimes provided to facilitate the flushing out of the last traces of air by passing degasified oil radially through the insulation. In all cases, the cable is completely dried and impregnated in the factory after leading, and shipment and installation without loss of oil is made possible by special pressure transportation reservoirs.

A cross-section of the oil supply reservoir is shown in Fig. 14. This reservoir is of the simplest type possible, with a single-unit metallic bellows enclosed in gas-tight metal casing. Severe tests have demonstrated these units to have a cyclic life far in excess of that required in service. The oil supply is contained in the bellows and pressure is maintained by gas in the outer casing. A light compression spring sufficient to overcome the inherent springiness of the bellows is used to supplement the gas pressure, and insures the oil pressure being always higher than the gas pressure, so that in case of a bellows leak the oil will leak outward into the gas instead of gas passing into the oil; and in addition, the bellows will be gradually compressed to the point where the low-volume contactor will operate.

Low-pressure and low-volume oil indicators are provided to operate mercury-tube contactors connected in the signal system. These signals are transmitted to a conveniently located control board which is equipped with a simple bridge by which the precise location of the trouble may be determined quickly.

CONDENSER JOINTS AND TERMINALS

The large increase in dielectric strength for a given thickness of insulation resulting from the use of oil filled cable has greatly increased the difficulty of producing satisfactory joints and terminals for use on commercial lines, and has resulted in the adaptation of the condenser type of construction to this purpose.

The development of a reliable and comparatively inexpensive stop joint, moderate in size and simple to install, is a most important feature of the oil filled cable system. The availability of such a joint simplifies the problems of oil feed, and of effective sectionalizing as regards oil supply. This joint utilizes the condenser principle, and in addition to effecting reduction in space requirements over earlier stop joints, it has shown electrical strength in excess of anything previously reported. By providing substantially uniform distribution of stress longitudinally it makes possible the use of the very simple "stop tube" arrangement. This construction reduces the joint insulation in the field to little more than a simple assembly process. In addition to the barrier-type terminals which have been used for a number of years on many commercial installations up to 66 kv., and on experimental lines up to 132 kv., terminals using the condenser principle are available also for the higher voltage.

The great problem in terminal and joint design is to prevent concentration of longitudinal stress in the neighborhood of the edge of the sheath, and to secure a substantially uniform potential gradient along the surface of the cable insulation between the conductor and the sheath. This latter factor is complicated by the fact that paper insulation has a low dielectric strength longitudinally in comparison with its strength radially.

For some time it has been recognized that stress distribution by means of a series of capacitances would be a complete solution for alternating potentials, but difficulties in the details of the practical application of this method have prevented its extensive use. These difficulties now have been overcome and two designs developed fully utilizing the condenser principle. In the design first produced commercially, and used for both joints and terminals, the condensers are annular and mounted on a tube which slips over the exposed end of the conductor insulation. The construction of a terminal of this type is shown in Fig. 15. Similar principles are used successfully in the design of joints.

NEW CONSTRUCTION MORE ECONOMICAL

A new form of construction has been perfected recently which is much lower in cost and which for joints has displaced entirely the earlier one. In this design, shown in section in Fig. 16, the condensers take the form of a nest of concentric metal cylinders *A* insulated from each other by saturated paper. At the ends of these cylinders are radial sections *B*, which are in effect conducting disks, terminating at their inner edges in short cones *C* which control the longitudinal distribution of voltage along the exposed cable insulation.

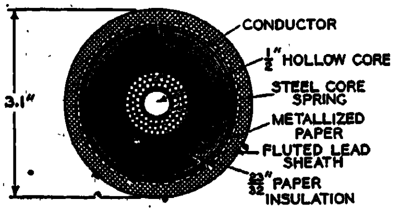

Fig. 13. Single-conductor oil filled cable for 132-kv. service

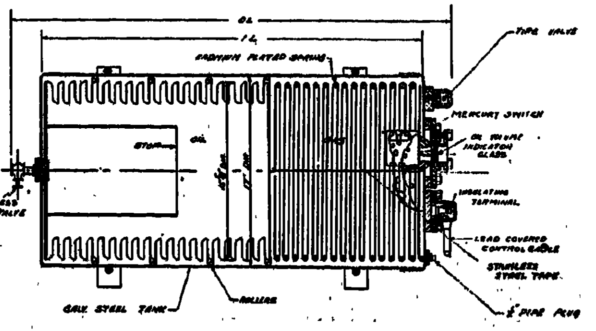

Fig. 14. Pressure type variable-volume oil reservoir

The capacity between successive cylinders and their corresponding potential is controlled by varying the insulation thickness between them, or by the use of several cylinders connected in parallel as shown at *D*. The angle of the conical portion is calculated to give substantially uniform potential gradient between adjacent cones, and to prevent concentration of stress at the inner edges. This angle is smallest near the end of the sheath and increases toward the center of the joint.

In practise, the complete group of condensers is built up as a separate, self-contained unit. A long strip of paper is wound on a tube of rigid insulating material referred to as the "condenser tube" thin sheets of metal being inserted at appropriate intervals to form the cylinders *A*. The inner cylinder is connected to the cable conductor through a metal ring inset in the tube, and spring contactors mounted on the splice connector. The cones *C* and disks *B* are formed by winding on with the paper, narrow metal tapes fed from spools which move longitudinally to the axis of the joint to produce the desired taper. When the winding is finished the complete unit is incased in a thin sheet of corrugated copper, vacuum dried, and then saturated with insulating oil and the casing sealed, thus forming a compact unit which can be easily handled and installed by simply slipping it over the joined ends of the cables.

The longitudinal stress in the oil films between the condenser tube and stop tube, and between the stop tube and the conductor insulation, is controlled by the condenser construction and by the angle of taper used on the conical metal socket into which the stop tube is mounted at the outer end. With very thin high-strength cable insulation, however, the radial stress on the film within the stop tube may be excessive. To prevent this, it is ordinarily found desirable to build up the conductor insulation with a tube of impregnated paper slipped loosely over the end of the cable and tightened up by twisting. In this way the radial stress in the oil films may be kept well below that which will produce ionization. This same construction is used also with excellent results in non-stop joints and in terminals of both the barrier type and the condenser type.

INCREASED LONGITUDINAL STRENGTH

By this construction it has been possible to obtain substantially uniform longitudinal distribution of stresses. The limiting feature of design has become the actual longitudinal strength of thin oil films and of the impregnated paper in a direction parallel to its laminations. In earlier designs of joints and terminals it had not been possible to develop this strength, and consequently there has been very little previous work to determine specific values of electrical strength in this direction. For this reason a large number of tests has been made on laboratory samples simulating the conditions found in the condenser unit and using oil films approximately 1 mil thick. When tested at 20 lb. per sq. in. gage pressure, a longitudinal strength of 40 to 60 kv. per in. was indicated. No reduction of strength with time of application of voltage was observed. Breakdown voltage was roughly proportional to the square root of the distance between electrodes, and to the eighth root of the absolute pressure. On completely assembled joints having a total of 14-in. longitudinal creepage distance, tests have been made up to 300 kv. for approximately eight hours without failure, and proportional results have been obtained on smaller joints.

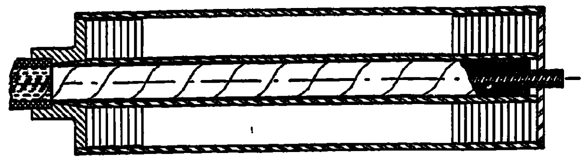

Fig. 15. Elements of test terminal with disk condensers

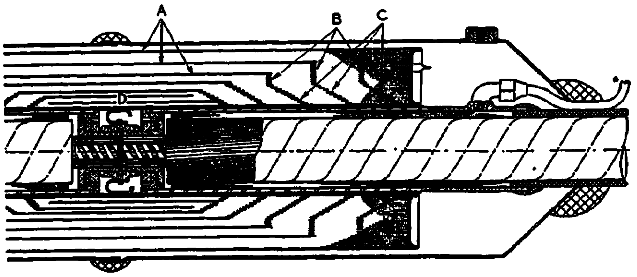

Fig. 16. Condenser joint with cylindrical condensers

In earlier designs of joints and terminals for very high operating voltage, the difficulty with concentration of stresses increased with increased voltage, so that a small increase in voltage necessitates an entirely disproportionate increase in dimensions. As a result, a rather definite limit was established beyond which further increase in voltage was impracticable. With the uniform distribution provided by the condenser construction, increase in voltage merely requires a proportional increase in the number of condenser steps and the design of joints and terminals for any desired voltage for which cables later may be built becomes a simple matter of adjustment of dimensions.

These developments have made possible a unified cable system combining the inherent advantages of the oil filled principle with certain features which contribute greatly to simplicity and reliability. These features include ease of installation, efficient sectionalizing, and provision for prompt detection of oil leaks or abnormal pressures. As a result, freedom from electrical failure, which is characteristic of oil filled cables, may be expected to be matched by freedom from service failures due to most of those external and mechanical causes which result in failures on the present solid systems.

The Transfer of Skill to Russia

A native of Russia, speaking the language and familiar with the customs and habits of its people, the author has come to the conclusion that Russia's principal problem in her industrial development is one of management. On the basis of 25 years of professional engineering experience in the U.S.A. and a recent 18-month professional engagement in Russia, this conclusion has been reached.

By
WALTER N. POLAKOV Consulting Industrial Engineer, New York

TO ACCOMPLISH the gigantic and ambitious program of changing within perhaps a few years the most backward country into a modern industrial land of Soviets is the aim and determination of the mass of the Russian population. The leaders of that country are charged with this tremendous responsibility and millions of workers, communists, and ordinary citizens are watching sharply every step toward the fulfilment of their Five Year Plan.

Last February the Conference of the Industrial Executives passed the resolution to accomplish this task in four years instead of five, and in the more essential industries in even three years. The speed of this progress was made the essence of the program. Stalin pointed out that in the past, Russia was defeated constantly because of its alluring richness and defenseless backwardness. Another reason for this acceleration is the dire need of consumers' goods such as clothing, shelter, and food, the shortage of which may be endured by the hardy and fatalistically inclined population for just so long, but not indefinitely. The third reason for this unheard of speed of development may be found, although it never has been admitted, in the psychology of the population. Four hundred years of despotic monarchy, browbeating officials, and economic slavery to landlords resulting in a low standard of living, were blended gradually with the passive slavic, almost oriental easy going slow tempo of the primitive agricultural life, so that in order to take the population out of this static inertia and accelerate it nothing but this kind of complete change to the great speed of preplanned activity would do.

The slogan "catch-up with, and overtake the leading industrial countries" coupled with the ambition formulated on banners and posters throughout Russia calling the people to become the "leaders of the world" gives them the courage to live in the anticipation of better days and easier life after the Five Year Plan is completed.

Meanwhile, they need machinery and the skill to use it. To build plants and factories and to open up the mines is relatively easy. To be sure, one needs cash or credit for the purchase of equipment, and as this must be bought in Europe or America, it involves export for exchange of Russian goods for foreign equipment. Since the world-wide industrial and financial crisis the prices went down, but the terms of orders previously placed remained. Hence, Soviets have to export more than they had planned in order to pay for the equipment under contract. This is obvious, and the people must put up with shortages of every kind at home.

Yet what is not so obvious is that after factories are built and machinery installed, goods must be produced. This constitutes a real problem and a particularly grave one under the circumstances.

COMPETENT MANAGEMENT NEEDED

Nowhere in the world is the old adage that, "large plants and perfect equipment is of no avail without proper management" as glaringly true as in Russia today. Since production rate depends primarily upon organization for execution of plans, it requires the executive direction and managerial skill and the technological knowledge and habits of modern industry.

In U.S.S.R. is found a remarkable political organization, but industry and politics are not congruent. To organize a revolution demands different qualifications from those necessary to organize production. The leaders of Russian development begin to sense this fact. Stalin bluntly pointed out on various occasions that his comrades failed to learn the technique of production management. He made this point very clear when the last year's records were announced, showing a 25 per cent increase of production, an unprecedented rate of growth, instead of the expected 31 per cent. This year's plan anticipates a further 41 per cent increase in production. Newspapers are full of appeals and warnings. Recently correspondents from Moscow heralded Stalin's new economic policy with the center of gravity shifted from construction and machinery to the operation and human element. This was inevitable. In our personal experience, a well equipped, fully manned machine tool plant raised its output more than 400 per cent in a few months by introducing the simplest methods of modern technique of management.

An address delivered June 18, 1931, before the New York Chapter of the Society of Industrial Engineers. *Not published in pamphlet form.*

What does it mean and what is the cause of it?

On the surface, it means that young Russian industry could save 75 per cent of the investment in new plants and factories if the other 25 per cent were managed properly, or that it could produce at least four times more on investments. But is this merely a theoretical consideration or is it a practical, immediate possibility?

In the past, the extent of Russian industry was insignificant when compared either with the natural resources of the country or with its present extension. This meant a relatively small number of engineers and executives. Many of that number are not available at present; some unwilling or psychologically unfit to render service under the vastly different social economic set-up. At the same time, hundreds of large industrial establishments being annually added and put into operation demand large cadres of executives and engineers. In parallel with the construction of new plants, Russia's plan provides for the establishment of new technical schools with short intensive training of a highly specialized engineering staff.

Most if not all large plants have technical schools under their aegis, seeing to it that young men and women are receiving necessary instruction in close contact with industry and meeting its needs. These students are workers themselves, with years of practical experience, working eagerly and tirelessly in various fields, gradually forming a new type of practical specialist so much needed in modern mass production based on standardized methods. Furthermore, foreign engineering contractors selling and installing equipment usually furnish instructors to demonstrate the use of their equipment and the process of manufacture.

But here the difficulty begins. Buying a machine on a guarantee basis so that it is capable of turning out such-and-such an hourly production, does not mean and cannot mean that the plant as a whole, even if completely and properly equipped with a full complement of productive and auxiliary equipment, actually will turn out the specified volume of finished product. The simple truth that such an efficient performance demands as an unconditional prerequisite a well-devised, systematic management and a competent executive control, is as yet not fully recognized by a sufficient number of the political and industrial leaders of that country.

SHOP EXPERIENCE LACKING

The lack of actual shop experience in administration and management and the enthusiastic belief in guaranteed "machine capacity" leads them to expect that the personal efficiency of workers alone can accomplish the desired results. Too often when there is a shortage of output or falling behind of production programs, the salvation is sought in the so-called "shock brigades," and not in the strengthening of the mode of management. These "shock brigades" are composed of volunteer workers pledging themselves to increase the production by all means within their power. They do, at least temporarily, a measure of good. By their enthusiasm and example they often improve the shop morale, reduce tardiness and absenteeism, make steady work during the shift socially respectable, provide stimuli for reduced spoilage, lower expense, and promote general economy; but they cannot and they do not bring order out of chaos. As a matter of fact, an efficient "shock brigade" frequently so outstrips the rest of the workers that the management without the aid of proper dispatching, scheduling, and control of the flow of production, finds itself facing an utterly unbalanced inventory of finished and semi-finished parts, with operating capital tied up and with the actual output but slightly improved.

It is difficult for those in America to realize fully the managerial handicaps so characteristic of the giant infant—Russian Industry. We hardly ever stop to consider what a predominant proportion of our industrial activities is carried by the established standard of procedure; how much specialized knowledge is available for the asking from a supply firm, sales engineer, or a foreman or superintendent with a vast experience elsewhere, and even from a competitive firm. We are in the habit of dividing the operating problems into two great classes: *routine* and *exceptions*. Under the first class fall all functions that are well standardized either by tradition or by analysis, all of these being handled by clerks and various supervisors. Under the second class we place all the unusual and emergency occurrences which fall under the jurisdiction of specialists or executives. They are relieved of all routine work, but as soon as production gets out of balance, supply is disrupted, personnel demoralized, distribution crippled, expenses and prices take a swing, or a new line of production is contemplated, these executives step in, mind-free from all the normal operating details which are left to the standardized functions of the routine men.

There is no such clear division of responsibilities in Russia. We read time and again in local papers, and ourselves have observed that in the plants managers having no information to rely upon and to be guided by, instead of taking their time and studying such methods, waste their time by walking miles and miles daily through the vast shops hoping mostly in vain, to find on these sightseeing tours some important items requiring their executive attention.

This absence, or near-absence, of an established routine of standardized procedure is of course a normal thing in a young industry grown almost overnight and having no past on which to base useful traditions. Nevertheless, the harm and waste resulting from this lack of functionalized division of responsibilities is very great; but the chances are that it soon will be in disrepute.

There is no doubt that Russians can learn things quickly. A group of Japanese undertook to teach them how to organize locomotive repair work with the result that what used to take weeks now is being done in a few days. We Americans showed them how to quadruple their machine-shop output without adding equipment or changing the design of the product, merely by getting the flow of work under control with the aid of Gantt charts and other purely managerial means. They begin to realize the importance of this transfer of skill. For instance, an American textile engineer was engaged to prepare a full set of standard practise instructions for the headquarters responsible for the organization of the textile industry.

All of us are familiar with that naive emotion which may be termed "the lure of the machine," that admiration of its almost intelligent working, that awe of its superhuman power, and that great expectation of the beneficial results to be derived from it. We learn, however, that the machines are a liability, not an asset, until brains are employed to organize their utilization. A million dollar plant producing $600,000 work of goods, if operated at half its capacity, causes $130,000 annual loss. Assume now that there is the demand for double the output. It can be secured by two means: double the plant at an investment of another $1,000,000 and increase the payroll by another $100,000, or else utilize the existing plant with double efficiency by means of modern managerial technique. Are such services worth, say, half of the $130,000 a year previously wasted because of the absence of such specialized skill, or is it more economical to incur an added obligation of $300,000 for the physical extension of the plant capacity under the old management?

Naturally, the European manufacturers seeking a market for their machinery in the rapidly growing U.S.S.R. are advocating the second method of new investments, suggesting at the same time that their unemployed technicians may go to Russia and transfer their skill, no longer needed at home, to demonstrate the operation of the important equipment for a compensation commensurate with the depressed hope of finding a job at home.

THE PROBLEM

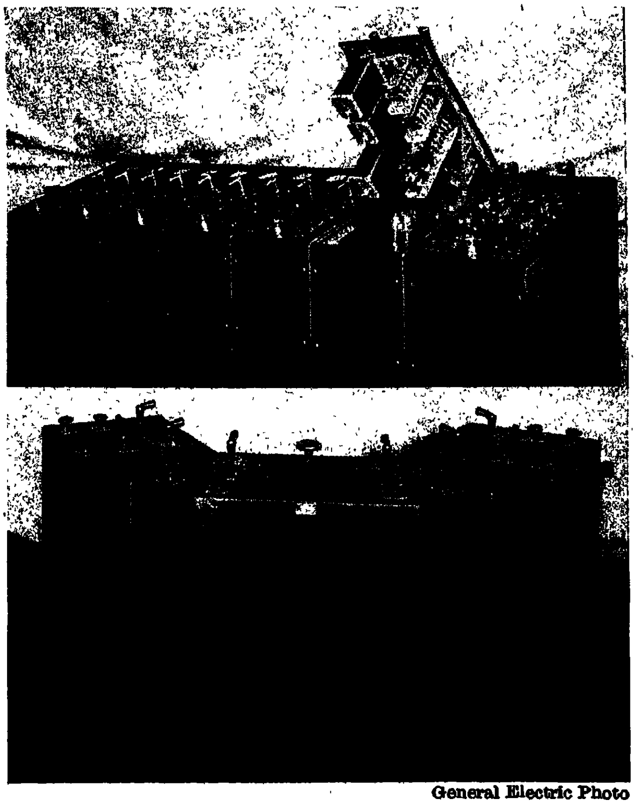
And then what? Mines are mechanized, new plants erected and equipped, factories rejuvenated by the new machinery, *but* the degree of their utilization, due to old fashioned organization, lack of administrative experience, and absence of management technique and executive training remain nearly as low, if not lower, than before the enlargement due to the dilution of the executive and managerial forces by the as yet inexperienced newcomers placed in charge of new plants and extensions.

Such seems to be the main problem confronting the fulfilment of the Russian "Five Year in Four Plan" today and its future destiny. There is an alternative: either to burden the country with an additional mass of the means of production for generations inadequately utilized, or to transfer the managerial skill, to accelerate the period of learning and, in the words of one of the vice presidents of the Supreme Economic Council of U.S.S.R., to get rid of that "ugly, oriental expectation of miracles from new machinery."

In the light of our American experience, especially since the days of Gantt, and in view of the European seeking of advice of American management engineers, it appears as a foregone conclusion that the U.S.S.R. must and will follow both roads. First she must build up the industry with essential equipment; but next, if she does not want to ruin the equipment by poor attendance, and if she wants to obtain full results from the investment made, she should definitely commit herself to the transfer of managerial skill on a par with the importation of machinery.

Upon this decision apparently rests the answer as to how well Russia will fulfil her Five Year production program.

Compact Industrial Control



General Electric Photo

SOME of the trends in industrial electrical control as exemplified by recent steel mill installations are indicated in the accompanying illustrations. A seven-panel control desk built for use in connection with a 65-panel switchboard may be seen in the upper illustration. This board although only 98 in. long, and 30 in. high in front, accommodates full control for nine large d-c. motors and five d-c. generators, motor controls including reverse, and fine and coarse speed adjustments.

Unity Power Factor For Neon Tube Signs

Application of parallel capacitance will not correct the power factor of the usual commercial neon tube installation to a value greater than 90 per cent. A constant-current circuit for use with these signs is described in this article, which not only operates at unity power factor but possesses other advantages.

By
J. K. McNEELY

State College, Ames

ATTEMPTS to correct the power factor of neon tube electric signs by the use of parallel capacitance have not been altogether successful. Although sufficient capacitance can be added to shift the apparent phase position of the current wave to the phase position of the voltage wave, this will not provide for unity power factor because of the non-sinusoidal nature of the current wave. While in most cases power factor correction for this type of equipment cannot be justified from the cost standpoint, nevertheless the circuit described here does provide power supply at unity power factor and without presenting any additional difficulties either of an economic or engineering nature.

OPERATING CHARACTERISTICS OF PRESENT EQUIPMENT

Since the resistance of a gaseous conductor tube is practically in inverse ratio to the current flowing through it, in order to limit the current its power supply must be received through a high series impedance. This impedance must of necessity be essentially reactance, as a direct power loss would result if resistance were used for this purpose. In the past this higher reactance has been obtained most economically by using a supply transformer with abnormally high leakage reactance. (See Fig. 1.). Low power factor results from the use of transformers of this character, being usually of the order of from 30 to 40 per cent.

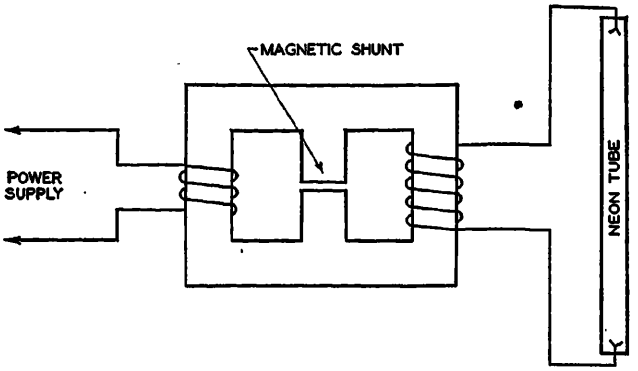

Fig. 1. Schematic diagram of ordinary neon tube installation with high-leakage-reactance transformer

When these high-leakage transformers are connected to lines having sinusoidal voltage waves, a current wave of non-sinusoidal form will flow as indicated in Fig. 2. The current wave in this particular case lags the voltage wave by about 72 degrees (31-per cent power factor) and was found to contain both third and fifth harmonics of appreciable magnitude. If capacity reactance be paralleled with the transformer primary in an effort to improve the power factor, the optimum power factor will be obtained when the fundamental component of the current wave is in phase with the impressed sinusoidal voltage wave. Under these conditions the harmonic components of the current wave will remain unaltered since with a sinusoidal impressed voltage, capacitance can draw only current possessing a sinusoidal wave. For this reason the best power factor which can be obtained in this manner is only from 80 to 90 per cent.

CONSTANT-CURRENT CIRCUIT

A number of constant-current circuits have been developed from time to time in the past, especially for application to arc-light service. One such circuit as described by Steinmetz in his "Theory and Calculation of Electric Circuits," has been adapted for neon tube operation. This is shown schematically in Fig. 3.

With this arrangement, current supplied to the transformer primary by the constant-current circuit will at all times bear a constant numerical relation to the impressed voltage regardless of the transformer impedance. Thus the high impedance of the transformer on no-load during the start of each half-cycle and before the breakdown of the neon tube load on the secondary will give secondary voltages of sufficient magnitude to induce ionization in the neon tube, if the transformer turn ratio be appropriate. As soon as secondary breakdown has been effected, the impedance of the transformer drops lowering the transformer primary voltage required to maintain the current to the point where the primary voltage times the turn ratio equals the secondary voltage required to sustain current flow in the neon tube.

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

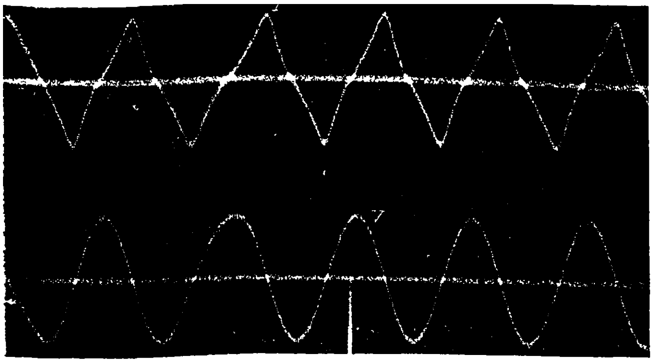

Fig. 2. Current (I) and voltage (V) waves for typical neon tube installation such as shown in Fig. 1

The oscillogram shown in Fig. 4 shows the current wave as taken from the line by this circuit with a sinusoidal impressed voltage. The current wave also is of sinusoidal form and is in phase with the voltage.

ADVANTAGES OF CONSTANT-CURRENT APPARATUS

A series of comparative tests were made to show the relative advantages of the constant-current circuit as compared to those of the high-leakage transformers now being used. In these tests the light output of the neon tube was determined by means of a photoelectric cell placed adjacent to the tube. A microammeter and a 90-volt battery were connected in series with the cell. The microammeter indications thus gave a measure of the light output of the tube. Since only comparative results were desired, the readings were used directly without conversion into equivalent light output.

Results of this series of tests are given in the accompanying tabulation. It may be noted that the proposed constant-current circuit gives a ratio of light output to watts input midway between those obtained from the two commercial transformers tested. Also the capacity reactance required to bring about the best power factor is lower for the constant-current circuit than for the standard commercial transformer circuits. Unity power factor was attained readily with the constant-current circuit while for the corrected standard commercial transformers the best obtainable was not over 90 per cent.

COST COMPARISONS

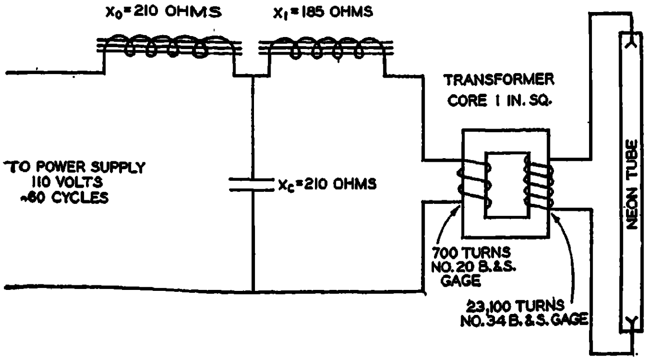
Although no accurate data are available showing the relative costs between inductive and capacity reactances for service demands such as those involved in this application, a careful estimate shows that the reactances used in the proposed circuit should cost somewhat less than the parallel capacity reactance required to furnish the maximum correction for a commercial type, high-leakage-reactance transformer.

The constant-current circuit requires less current in its transformer primary winding than does the corrected

Comparison Between Constant-Current Circuit and High-Leakage-Reactance Transformers

Item	Constant-Current Circuit	Commercial Transformer No. 1	Commercial Transformer No. 2
Minimum primary current, amperes (r. m. s.)	0.265	0.350	0.354
Power factor, uncorrected	1.000	0.319	0.312
Best power factor obtainable	1.000	0.908	0.808
Capacity reactance required, μf	12.45	21.40	19.20
Power in watts	30.40	36.23	32.45
Secondary current, milliamperes	15.00	15.00	16.10
Secondary milliamperes per watt input	0.493	0.413	0.496
*Photoelectric current, microamperes	9.90	9.90	11.10
Photoelectric current/watts input	0.326	0.272	0.342
Same as above, with maximum power factor correction	0.326	0.286	0.359
Photoelectric current/amperes line current	37.30	38.30	31.30
Same as above, with maximum power factor correction	37.30	10.30	12.50

*These readings not translated into equivalent light output since comparative results only were desired.



X₀=210 OHMS

NEON TUBE

Fig. 3. Constant-current circuit for supplying neon tubing at unity power factor; constants used in the experimental set-up are shown

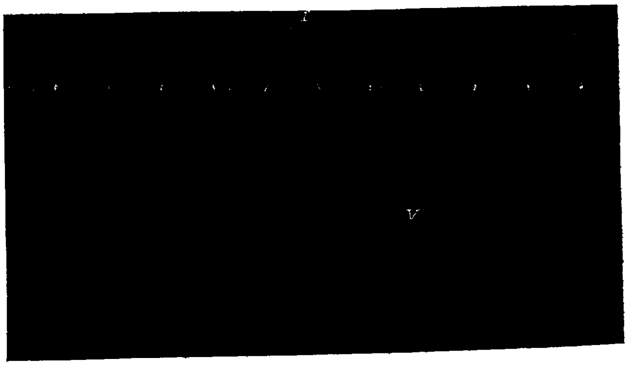

Fig. 4. Current (I) and voltage (V) waves for constant-current circuit of Fig. 3. Note "in-phase" sine-wave current

or uncorrected magnetic-shunt type of transformer now in use. Thus a smaller size of wire may be used in the primary circuit of the transformer used in the constant-current circuit with a corresponding additional saving in cost.

In addition to the advantages already mentioned, it is necessary to mount only the transformer of the constant-current circuit on the neon tube sign itself; the reactances may be mounted inside of the building. The constant-current transformer has the further advantage of requiring less space than the magnetic-shunt type.

As stated at the outset, the general use of corrective circuits or other means of raising the power factor of gaseous conductor lamps cannot be justified in most cases from the standpoint of economy. However, the solution presented here corrects some of the defects or errors of the earlier solutions without presenting additional difficulties either of an economic or engineering nature.

Operating Experiences with Automatic and Supervisory Control

Records have been kept by three different investigators on various types of automatic equipment for station control. These results are summarized in the following articles.

PROGRESS in the development of automatic equipment and in its application to the control of electrical energy has followed very closely the phenomenal growth of the industry itself during the last decade. Automatic equipment was applied first to the control of small outlying transformer stations. As the success of these installations was established and new control schemes and devices were developed, the application has been extended to include practically all types of stations. The chief reasons for this wide popularity are that the first cost of the station is increased but little while reliability and flexibility are as good if not better than with an attended station, and operating costs are materially less.

In the group of three articles following, the experiences of several years' operation on different types of equipment for automatic and supervisory control of railway substations, a-c. distribution substations, and generating stations are presented. The authors of each article have given a summary of records on their equipment, kept over a period of years and presenting principally the operating troubles most frequently experienced.

Automatic Control of Substations

By
GARLAND STAMPER
Associate A. I. E. E.
Columbia Engg. & Management Corp., Cincinnati, Ohio

AUTOMATIC and semi-automatic stations of various types have been in operation during the past ten years on the system of the Columbia Gas and Electric Corporation. These stations include transformer substations for distribution at both 13,200 and 4,325 volts, street railway and Edison system synchronous converter stations, and synchronous condenser installations.

The distribution substations have been equipped with automatic reclosing oil circuit breakers and automatic induction voltage regulators on the feeders, with load-response equipment included in the transformer bank control. The street railway converter stations and two Edison system motor-generator sets are completely automatic in operation. The control of the converters is designed to function on voltage variation

---

From "Operating Experiences with Automatic Stations, Part I—Columbia Engineering and Management Corporation" (No. 31-94) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

and load demand, and includes many other features incorporated in the latest designs for this class of equipment; the circuit breakers on the d-c. feeders open on rate of rise of current and reclose when the circuit is clear. The synchronous condensers and all Edison system synchronous converters are equipped with semiautomatic control. This scheme includes complete starting operation when initiated by the operator, voltage regulation, load-limiting devices and other protective functions. The operation of any protective device in an automatic station transmits a signal to the office of the system load dispatcher.

It is realized that the class of service secured from any type of automatic station is dependent directly upon the excellence of inspection and maintenance. In the Cincinnati district there are five automatic-station operators, carefully selected and trained; their duties include the inspection and maintenance of fourteen stations. An effort is made to have an operator visit the more important stations once a day and the smaller stations two to three times a week for a regular inspection. This inspection consists of making the necessary meter and operation counter readings, adjusting graphic meters and changing the charts, adjusting battery-charging equipment, checking temperatures and general operating condition of all apparatus, checking indicating lamps, fuses, and grounds on control circuits, and in the case of rotating equipment observing the starting and stopping sequence. Once each week the rotating apparatus and all of its control equipment is cleaned and if necessary repaired, and a complete check is made of the proper functioning of all devices. Once every two weeks the equipment on each reclosing feeder is given the same general overhauling. Once each week all the control batteries are given a slight change and their condition checked. Finally, twice a year all the apparatus in the station is given a complete overhauling by the regular maintenance crew under the supervision of the automatic substation operators.

Upon looking back over the operating records of the distribution stations it is noted that at least 90 per cent of the faults on a circuit are temporary in nature and that the breakers remain closed after the first or second operation. These circuits having automatic reclosing circuit breakers are equipped with instantaneous overcurrent relays set to operate at a predetermined value of current which is slightly below the safe rupturing capacity of the circuit breaker, or the thermal capacity of the regulators. The operation of these relays prevents the reclosing of the circuit breaker until the fault has been cleared and the relays reset. To date there has been only one operation of these relays, which was caused by a cable failure near the station. By the use of such relays it is considered safe to install equipment having lower capacity, or to make the time between circuit-breaker reclosings less than otherwise advisable.

On the system of the Dayton Power and Light Company several automatic distribution stations are in operation. These stations are of the outdoor type having reclosing circuit breakers equipped with a-c. motor-operated closing mechanisms and 24-volt d-c. trip coils. So much trouble has been experienced with this type of control that except for special cases no similar equipment is being considered for future installation. The auxiliary switches are a source of perpetual annoyance and the centrifugal closing mechanism has a tendency to lose its adjustment and cause the breaker to "pump," or else fail to close altogether. It has been decided that future installations of this nature will include solenoid-operated breakers with a control battery, or some similar source of supply. Since the cost of the solenoid mechanism is less than the motor mechanism, this compensates to some extent for the additional cost of the control battery.

One of these stations was supplied through a tap connection on the double-circuit 33,000-volt loop around the city. Approximately two years ago this station was rehabilitated and 33,000-volt sectionalizing equipment was installed. At this time the control scheme was changed from automatic to supervisory, and is operated from the dispatcher's office approximately four miles distant from the station. The only source of trouble experienced on the installation to date has been due to interference by the telephone company from which the interconnecting wires are leased. Another point of some interest in this station as well as in automatic stations in general is the use of diverter-pole-type motor-generator sets for control battery charging. In case of complete outage of the station it was found that this set could be started automatically and reconnected to the battery without super-

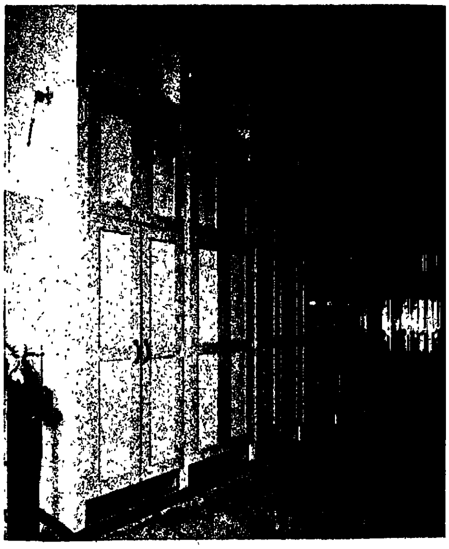

Fig. 1. Typical regulator structure showing installation of Lux fire extinguisher

vision. It is the practise at all times to float the motor-generator set across the battery.

In addition to the above stations this company has been operating four automatic street railway converter substations for approximately ten years. A great deal of trouble was experienced with these installations due principally to the use of the old plunger and bellows types of relays. These were not as accurate or reliable as the present induction relays and motor-operated timers. Practically all the original relays have been replaced by relays of later design and very little trouble from this source is anticipated in the future.

Listed in the order of frequency of occurrence, the chief items of trouble experienced in these automatic stations are: (1) improper adjustment of graphic meter pens and clocks, (2) loss of adjustment of circuit breaker auxiliary switches and closing mechanisms; (3) grounds on control circuits; and (4) relay troubles due to obsolescence and loss of adjustment.

It is to be concluded from the results of these experiences that when properly operated, the automatic station is equal to and in some respects superior to attended stations in reliability and flexibility. On the whole it is found that automatic equipment will perform the necessary functions more accurately and faster than could be expected of any operator. This results in an improvement in continuity of service by decreasing outage time, thus increasing revenues as well as good-will. At the same time, the duties of the system load dispatcher are lightened, permitting him to give his attention to the more important matters in times of major system disturbances, with a resultant increase in total system efficiency.

Automatic and Supervisory Control of Substations

By
F. F. AMBUHL
Associate A. I. E. E.

Toronto Hydro-Electric
System, Toronto, Ont.

THE POLICY of the Toronto Hydro-Electric System is to locate moderate-sized distribution stations near the economical load centers and equip them for automatic or supervisory control. These automatic and supervisory equipments include all the more prominent types as well as equipment developed by the Toronto system for its own use. In addition there is at present a Gamewell signaling system which is used for giving signals to the load dispatchers when switches open automatically in small unattended transformer stations where supervisory control has not been provided.

The automatic control for synchronous converter stations is arranged to start the converter on load demand determined by a contact-making voltmeter, and to shut down the unit when the load is reduced to an economical point. Two schemes are used on the Toronto system for accomplishing this result; the General Electric scheme in which a drum controller initiates the various operations in proper sequence, and the Westinghouse scheme in which these steps take place through the guidance and control of relays and interlocks functioning according to a predetermined plan in a step-by-step fashion. Both types of equipment have given satisfactory operation for over nine years, although a few troubles have been experienced. The principal difficulties with General Electric equipment are as follows:

1. When first installed the timing relays gave trouble and had to be replaced.
2. The field relay did not function properly, and required a new coil.
3. Some trouble has been experienced with the brake-bands on the brush-lifting mechanism, making replacement necessary.
4. An open circuit in the exciter generator used for correcting polarity occasioned considerable operating difficulty before it was known that this was the trouble.

With the Westinghouse scheme most of the troubles occurred during the first year, and since their elimination the equipment has given very satisfactory operation. The troubles were as follows:

1. The latching relay on the oil switch required modification.
2. Trouble was experienced with the contacts of the auxiliary switches controlling the main contactors, making it necessary to modify these devices.

From "Operating Experiences with Automatic Stations, Part II—Toronto Hydro-Electric System" (N . 31-94) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

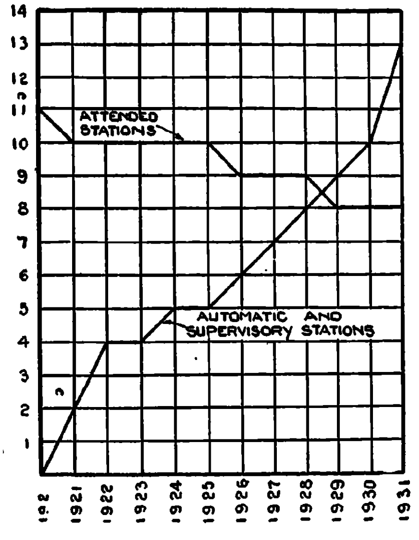

Fig. 3. Number of supervisory and automatic stations compared with attended stations

3. The contactor coils burned out repeatedly, and finally were rewound with a larger number of turns to avoid overheating.

4. Converter-bearing thermostats became inoperative due to warping of the fiber plunger rods.

5. The brush-lifting motor burned out, requiring replacement.

6. The brush-lifting mechanism gave considerable trouble, and had to be modified.

7. N little trouble was experienced with the arcing over of contacts on the polarized motor relay. These contacts had to be modified before the trouble was eliminated.

The two 1,100-kw. mercury-arc rectifiers manufactured by the Brown Boveri Company are fully automatic, the automatic features including (a) plant control whereby either unit may be made the leading unit while the other is switched in or out according to the demand on the station; (b) a-c. closing and reclosing whereby the circuit breaker connecting the rectifier transformer to the a-c. supply is controlled; (c) vacuum-pump control; and (d) the protective group. This rectifier equipment has given very satisfactory operation although some operating troubles were experienced when the apparatus was first installed. These were:

1. Insulator on excitation anode was found cracked due to incorrect size and improper packing.

2. Ignition coils burned out several times due to relay sticking, but this was overcome by modifying the relay.

3. Poor contact on control relay prevented the rectifier from being cut in.

4. Trouble on overload relay contacts prevented the second unit from coming in.

SUPERVISORY CONTROL EQUIPMENT

The Westinghouse high-speed, visual, supervisory-control system is an all-relay system embodying the principle of step-by-step synchronous selection. This system has been installed in four stations, the first having been installed six years ago, the second four years ago, and the other two, three years ago. This equipment although not entirely free from trouble has given satisfactory operation. In almost every instance, however, the troubles experienced are of minor nature, and usually are found to be due to contacts or relays requiring slight readjustment. Control-key contacts, battery equipment, and fuse troubles also contribute to faulty operation.

In the Danforth station 45 cases of relay troubles were reported in five years. Fourteen of these were due to latching relays sticking. Operating records of the other stations using the same kind of equipment, but of more recent date, do not show the latching relays to have given any more trouble than other relays.

The distributor-type supervisory-control system of the General Electric Company was installed in the Parkdale station in 1928. This was one of the early developments of supervisory control and uses a modification of the printing telegraph distributor and polarized relays to minimize the number of connecting line wires between stations. Due almost entirely to the distributor mechanism considerable trouble was experienced with this type of equipment.

The motor-driven distributors, one installed at each end of the control system, were operated continuously and had to be kept in synchronism if proper operation of the control system was to be obtained. Numerous faulty operations were experienced as a result of this part of the equipment getting out of order, and it was finally decided to change the system to the more recent development known as the synchronous-selector type of supervisory control. This new system, which replaced the distributor-type supervisory control in the Parkdale station, is essentially a direct system of control and indication employing the familiar type of rotary selector used for automatic telephones, which step in synchronism to transfer the control and indication line-wires from one circuit to another as selected by the dispatcher. This synchronous-selector type of equipment has been in operation since April 1930, and has given very satisfactory operation. Only two relay troubles have been experienced during the first eight months.

A cable system of supervisory control which was developed by the Toronto system for its own use is

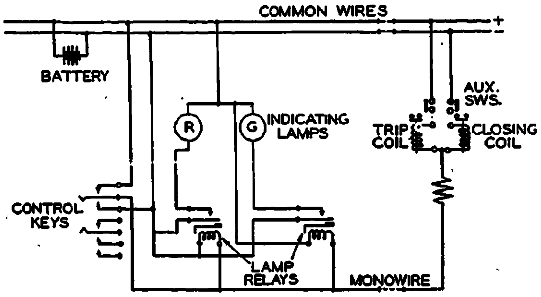

Fig. 6. Monowire scheme with indicating features

installed for four stations. It has been called the Monowire type of supervisory control, since in addition to two wires which are common to all control units it requires only one wire for each unit to be controlled. Control of the units and an indication of their operation can be secured by this system, simplified diagrams of which are given in Figs. 5 and 6. In complete commercial circuits, additional lines and safety features are added. Although the diagrams show control for one unit only the scheme may be extended to any number of units desired.

During the past ten years this system of control has given very satisfactory operation. There has been very little trouble with the switch operation, although a certain amount has been experienced with the signal devices. Most of the trouble was due to faulty relay operation. The relays used in this system are standard and have been tested under most severe operating conditions. Troubles have been due to a number of causes, such as residual adjustments, faulty contacts, loose nuts and screws, dirt, etc., all of a minor nature. A few sources of trouble have occurred with control-key contacts, battery equipment, poorly soldered joints, loose fuses, blown fuses, etc. Relay equipment purchased recently has given much less trouble than the earlier equipment, indicating that the manufacturers have overcome troubles experienced with the earlier designs.

This cable supervisory system finds its widest application where the distance between stations is short. The very satisfactory operation secured with this scheme has resulted in its being used on the Toronto system where the total cost of installation, including supervisory cables, was less than other schemes using synchronized switches at the sending and receiving ends. It is so much more simple and reliable than the other systems that its use seems justified wherever cost will permit.

Supervisory Automatic Control of a Generating Station

By
R. M. STANLEY
Fellow A. I. E. E.
Byllesby Engg. & Management Corp., Chicago

EIGHT hydroelectric units, each having a capacity of 13,508 hp., are installed in the Ohio Falls hydroelectric station at Louisville, Ky. Each generating unit is complete in itself. Waterwheel, generator, exciter, governor, electrical control, oil and water supply, oil circuit breakers, etc., are individual to each

---

From "Three Years' Operating Experience with Miniature Switchboard Supervisory Automatic Control" (No. 31-109) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

unit and all related unit auxiliaries are fed entirely from that unit.

An automatic electrical control unit and a hydraulic control unit are located near each generator. The electrical control equipment is similar to that used in other stations but is placed inside of a sheet steel cubicle located adjacent to the governor. For all units in the station, there is a centralized supervisory control switchboard of the miniature type located near the center of the plant, with a multi-conductor telephone cable between the miniature board and each generator control unit. The miniature supervisory board resembles in some respects a manually operated telephone switchboard. The arrangement of control keys and indicating instruments on 4-in. panels places the control of all generators, transformer banks, etc., within convenient reach of the operator.

The advantages of supervisory and automatic control have been demonstrated clearly during their three years of operation. With the miniature switchboard, the operator is at all times closer to indicating instruments, control switches, etc., and can give better and closer supervision to the operation of the equipment. This results in better voltage control, frequency control and division of load among the generating units. The supervisory control and automatic features give another distinct advantage in that there is a great saving in time during normal and emergency operation, and to a large extent human error is controlled. When urgently needed a hydroelectric unit can be brought to speed and synchronized in one minute, and additional units can be put on the bus in approximately 30-sec. intervals thereafter. Due to this speed, it has become the practise to carry less reserve steam capacity when hydro units are available.

There is a marked saving in labor costs since only one shift operator is required for the entire station. In addition, supervisory and automatic control made it possible to reduce the initial capital expenditure and to lower fixed charges.

The miniature board is no more costly to maintain than any other type of switchboard; in fact, a comparison with maintenance costs on a benchboard and vertical board with full-sized instruments, control switches, etc., at Waterside steam station indicates that the maintenance and inspection cost of the miniature switchboard and automatic equipment is less. As most of the equipment is enclosed in a practically dust-proof cabinet very little cleaning has to be done.

SCHEME OF CONTROL

The general scheme of control is that the turning of a miniature control key or pushing of a button at the miniature supervisory board sets in operation automatic relays associated with the unit being supervised. These automatic relays, of the polarized type, function in a predetermined sequence for each desired operation, such as the starting or stopping of a generator, or connection of a transformer bank. A remote indication of the kilowatt load, reactive voltamperes, and voltage on each unit is given on miniature instruments. For the generators these are direct-connected to the instrument transformers, and on transformer banks, Selsyn type miniature instruments are used.

On starting a generating unit the supervisory operator turns a key which selects the proper bus and synchronizing method. He then pushes a button which gives the starting impulse to perform the following functions: maintain governor oil pressure; release brakes; open gates; apply generator field; energize governor motor from generator supply; start generator air-cooling system; and synchronize the generator to the bus selected. The supervisory operator may then regulate the load, voltage, and reactive voltamperes.

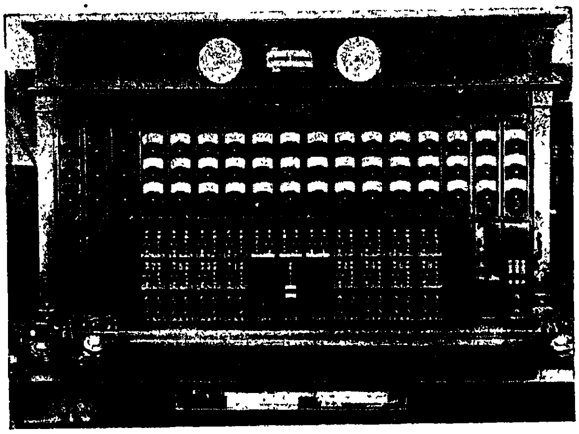

Fig. 7. Miniature switchboard for supervisory control of all generating units in station

While in operation a full set of protective equipment is in use, and when the operator desires to shut down a unit the procedure is somewhat similar to that of starting. The equipment is tested only at intervals of three or four months when it appears necessary to clean the equipment.

Over a period of three years there have been no failures in the supervisory cable conductors. The push-button for control of load and voltage are similar in construction to telephone jacks, and have given very little trouble. A few cases of trouble were experienced with the rotating type keys used for giving the starting impulse, for selecting the proper bus and method of synchronizing, and for opening or closing oil circuit breakers. These troubles were all traced to insufficient spring tension, and no failures have occurred since proper adjustment. There has been only one unusual case of trouble with the polarized relays energized from the keys on the miniature board. This developed in summer when the relays were subjected to an ambient temperature of 50 deg. cent. and the impregnating compound in the coils tended to vaporize and deposit on the armature, causing sticking in one position. This type of coil was changed and no further trouble was experienced. No cases of trouble have occurred with the sturdier contactors used for voltage and load control.

With the generator protective equipment very few difficulties have occurred. Practically all of these which could be attributed to manufacturing defects resulted because of vibration.

SYNCHRONIZING METHODS

Generators may be synchronized to the bus by two methods; (1) through self-synchronizing equipment wherein the machine is brought up to speed, the armature is closed in on the bus, and the field applied instantly thereafter; (2) automatic synchronizing relays which approximate closely the manual method of synchronizing. The speed of the incoming machine is regulated to match that of the running machine and when the phase-angle between the voltage of the two machines is satisfactory, the machine is closed in on the bus.

Each method has its advantages. The self-synchronizing method is faster, requiring about one minute to bring a machine up to speed and synchronize; this is generally used when the system capacity is large and the head of the river is above 20 ft. Oscillograms taken during synchronizing indicate that the current in the armature varies from one and one-half to twice normal. This dies down rapidly and generally reaches normal value in ten cycles. At the Waterside steam station a slight dip in system voltage equivalent to about one volt on a 110-volt basis occurs. The "bump" given the system during these conditions therefore is found to be not objectionable and the self-synchronizing method is used whenever possible. It has a further advantage over automatic synchronizing in that it enables a generator to be pulled into step during periods of severe system trouble when the frequency is below normal. The automatic synchronizing equipment is used only when the output of the hydro station is small due to the low head. The majority of synchronizing operations with this equipment require from two to three minutes from the time the unit is started; but very exact synchronizing results.

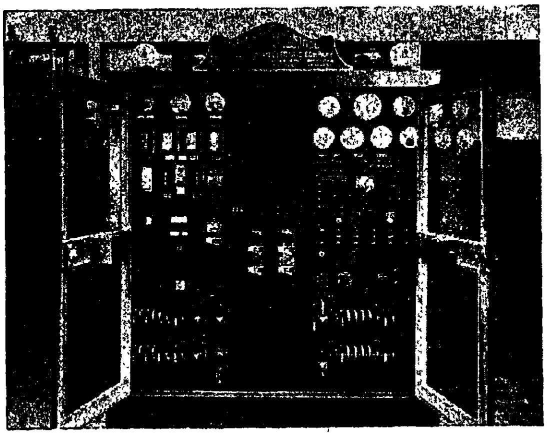

Fig. 8. Individual generating unit switchboard

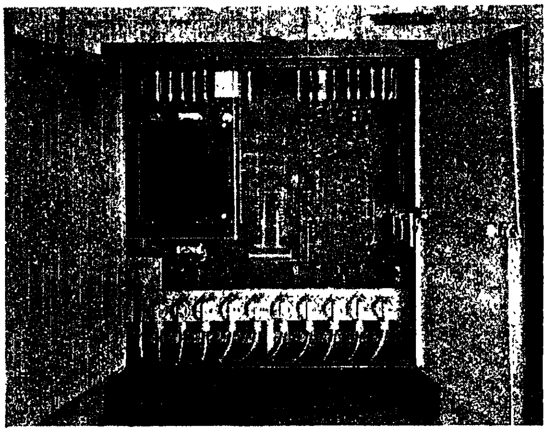

Fig. 9. Rear view of generator switchboard

To date there have been five system disturbances which resulted in the hydro station dropping load. These disturbances all occurred before the generators were equipped with self-synchronizing equipment; therefore, in cases where the automatic synchronizing equipment did not function rapidly enough, the operator put the machine on manually in order to save time. A maximum of four minutes was required to get the last generator on the bus. Now that the much quicker method of self-synchronizing is installed for all generators, it is being used almost entirely.

Each disturbance was caused by a short circuit of considerable magnitude, and when the circuit breakers opened, the overspeed of the generators and consequent rise of voltage was sufficient to operate the overvoltage protective relays, thus removing the generators from the bus and shutting the units down.

The operating experience obtained with the supervisory and automatic control at this station during the past three years indicates definitely the advantages of this combined system. The use of automatic devices has demonstrated its reliability, low cost of maintenance and inspection, the saving of time and operating expense, and the ease of supervision and operation. It is believed that in hydro plants where units are taken off and put on the bus frequently, this type of control equipment not only is superior to manually operated equipment, but that the plant will be operated with greater safety to equipment.

Communication in the New Waldorf Astoria

Said to be the most completely equipped hotel ever built, this new edition of a famous old hostelry contains the largest array of electrical program distribution equipment ever installed in one building. Included also in its communication system are approximately 3,700 telephones and 66 teletypewriters; 125 trunk lines connect the hotel with the telephone central office.

THE LARGEST program distribution and public address system so far brought together under one roof has been installed in the new Waldorf Astoria Hotel, recently opened in New York. Six separate channels are provided over which six different entertainment features may be distributed simultaneously both to the 1,940 private rooms and also to the many public rooms. This hotel occupies an entire block in the heart of the city and has a total height of 640 ft., including the 42 floors, and the two 100-ft. towers. It is considered to be the most completely equipped and most modern hotel yet constructed.

In addition to the program distribution facilities, the Bell system has arranged a communication installation which is said to be the most extensive ever placed into service in any hotel. Two groups of telephones have been installed, one to serve principally the hotel guests, the other to be used by the management for administrative purposes. To supplement the facilities for transmitting the spoken word, the hotel has been equipped with 66 teletypewriters. The entire communication system is served by 125 trunk lines from the telephone central office.

PROGRAM DISTRIBUTION SYSTEM

Features to be distributed over the six channels of the program distribution system may originate from any of the following sources:

1. Programs picked up by standard condenser microphones in any of the various public rooms.
2. Radio programs picked up by any of six Western Electric 10-A radio receivers.
3. Recorded programs reproduced on double turntable reproducer sets, of which two have been provided.
4. Wire line programs brought in from the outside.

A schematic diagram of the complete system may be seen in Fig. 1, all of the apparatus shown being housed in a control room on the sixth floor of the building. On the left may be noted the various program sources. Immediately to the right of these may be seen a bank of three-channel "mixers" and speech amplifiers. By means of these the input from as many as six microphones at one location may be blended together and amplified before going to the main amplifiers. Circuits are provided whereby the operator in the control room can communicate with an "observer" in any public room in which a program may originate.

For the six main amplifiers, one for each channel, Western Electric type 59-B units are used with the usual volume indicator, monitoring headset, and switching controls. The amplifiers operate entirely on alternating current, and possess practically a flat frequency characteristic between 20 and 10,000 cycles.

The power amplifiers consist of 31 Western Electric type 57-A units, 24 of which are used for guest room service, six for the public room circuits, and one for broadcast amplification. Each of these amplifiers has an undistorted power capacity of +32 db. above a zero level of 6 milliwatts. Means are provided for switching the output of these power amplifiers to the various circuits and for matching impedances.

Program circuits to guest rooms are distributed from a central distribution box through lead covered cables to outlet boxes in three riser shafts, the first extending the full height of the building, the second to the 21st floor, and a third to the 17th floor. Three 152-pair cables of No. 16 B&S gage wire are installed in these shafts, two in the first and one in the second, with a similar 102-pair cable in the third shaft. Distributing boxes are provided on the various intermediate floors wherein wires from the cables terminate in sealing chambers. From these boxes circuits are distributed throughout the floors with a maximum of four groups connected to any one riser pair and a maximum of twenty rooms connected to any one group.

For the private rooms special loudspeakers were developed which can be plugged directly into the program distribution outlets. Each speaker is provided with a six-channel selector switch and a volume control. The energy level to the speakers is held in the main control room to such a value that the maximum output from any speaker will not be sufficient to annoy guests in adjacent rooms.

One of the outstanding features of the entire installation is the flexibility of equipment and complete interchangeability of all major elements. All units such as radio receivers, main amplifiers, power amplifiers and distribution units terminate in jacks so that they can be "patched" into a variety of different positions in the circuits. In addition the system has been so designed and laid out that maintenance problems will be simplified as much as possible and that in the event of trouble the affected portion of the system can be segregated readily.

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

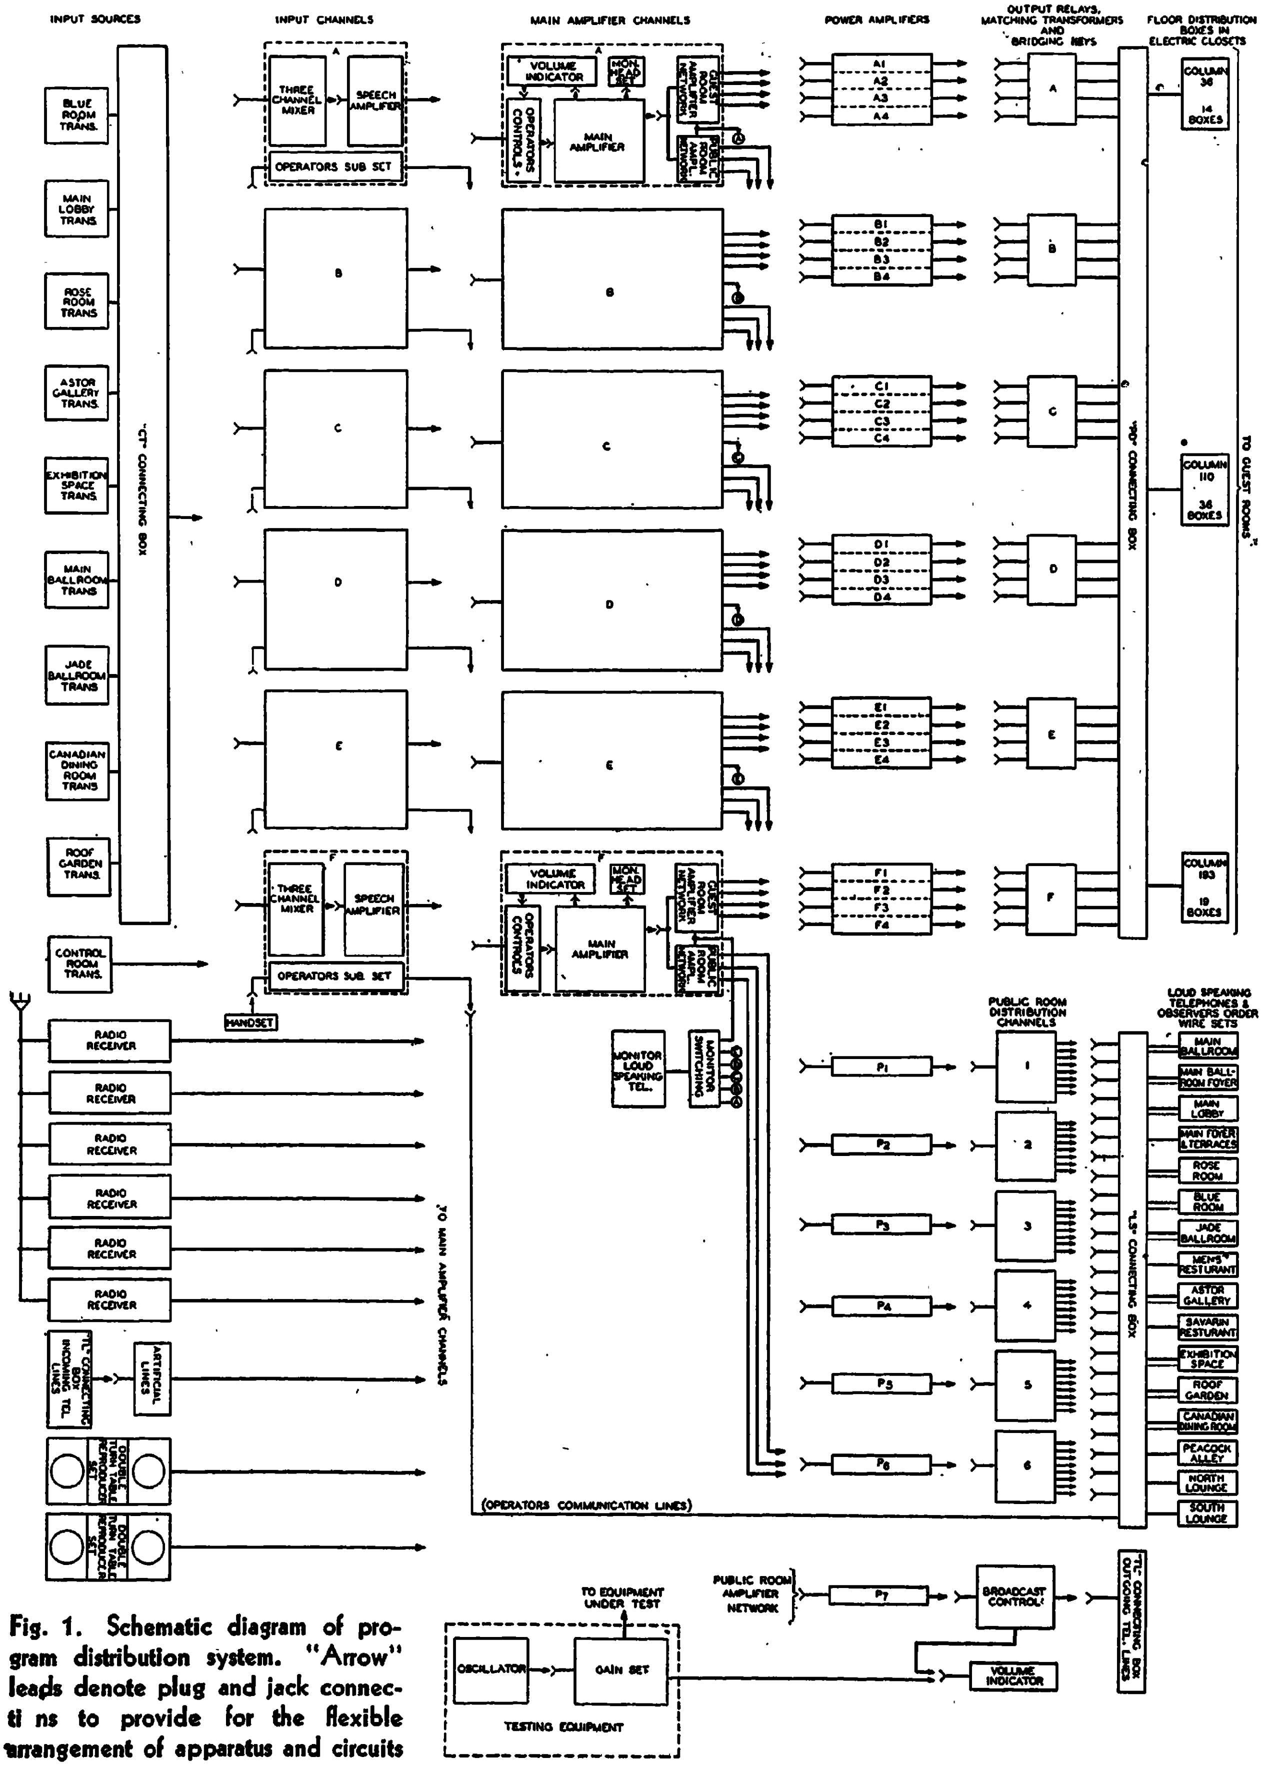

Fig. 1. Schematic diagram of program distribution system. "Arrow" leads denote plug and jack connections to provide for the flexible arrangement of apparatus and circuits

The entire program distribution system as well as the radio distribution system described in the following paragraph were designed by Bell Telephone Laboratories. The equipment was furnished by the Western Electric Company.

RADIO DISTRIBUTION SYSTEM FOR TOWER SUITES

In addition to the main antenna serving the six radio receivers of the program distribution system, two other antennas have been installed between the hotel's two towers. Specially shielded radio frequency distribution circuits connect each antenna to 69 tower apartments so that occupants of these suites may operate their own individual radio receivers therein. To operate such a large number of miscellaneous receivers from a single antenna without interference presented a difficult problem, the final solution of which consisted of supplying a separate radio frequency amplifier for each individual receiver. The circuits are so arranged that these coupling amplifiers are controlled by the same switch which controls the individual receivers themselves. Thus none of the amplifiers is turned on when not in use.

POWER SUPPLY

Since all electric power for the entire hotel is supplied from a d-c. system, special arrangements were necessary to furnish the program equipment with alternating current. For this purpose two 15-kw. motor-generator sets were installed in the power room on the seventh floor of the building, one being for regular use and one held as a spare. These are provided with automatic speed control to maintain proper frequency (60 cycles) and may be started, stopped, or otherwise controlled from either the power room or the control room on the floor below. These units are large enough so as to assure close speed and voltage regulation, and an unusually undistorted voltage wave under full system load.

OTHER EQUIPMENT

While the program and radio frequency distribution systems perhaps constitute the most novel features of the whole communication system, the telephone and teletypewriter systems are just as complete. They embody the latest developments in telephone engineering adapted to the needs of a modern hotel. The telephones may be divided into two main functional groups: one a manually operated system to serve the guests of the hotel, the other a dial system for use by the management.

About 3,200 telephones are provided for the use of guests in addition to the private telephones in the tower apartments served by individual lines from the central office. Of this total number about 2,600 are permanently connected extensions from a 28-position private branch exchange switchboard. The remaining 600 are portable instruments and may be conveniently plugged into auxiliary outlets with which some 600 of the rooms are equipped.

The telephone group for use by the management includes dial equipment sufficient to serve about 500 telephones in the executive offices, corridors, pantries, and other quarters occupied by the hotel personnel. These telephones may be interconnected with any of the manually operated instruments through the private branch exchange switchboard.

The teletypewriter installation comprises 66 machines, these also being divided into two main groups. The first group of these will be used primarily for transmitting to employees in every department concerned with their service, information pertaining to the arrival, change and departure of guests. The second group is provided with auxiliary order-taking equipment so that operators of the machines may take messages intended for guests directly from persons calling, and transmit them by wire to the guest's floor to be delivered when he returns, or to the bell captain so that the guest may be paged. With this system written messages may be transmitted from any of the sending machines in the telephone room to receiving machines accessible to the bell captain, porter, tower housekeeper, room clerk, valet, or to other receiving machines located on 22 floors, and in the tower office.

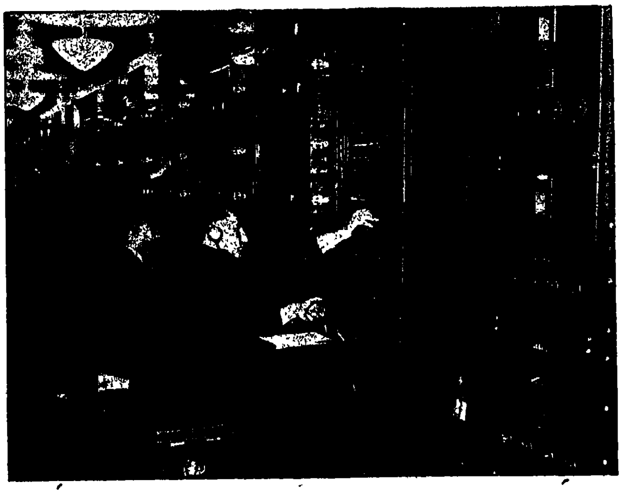

Fig. 2. General view of control room showing some of the 22 racks of amplifiers and other program equipment. Three of the six rack-mounted radi receivers may be seen at the right

Although not strictly concerned with communication equipment it may be mentioned that sound picture apparatus of the theatrical type has been installed permanently in the grand ballroom. Also one portable machine has been provided with which talking picture entertainment or lectures can be taken to any of the smaller public rooms.

Corona Versus Conductor Surface

Tests show that thin coatings of some materials reduce the corona losses from high voltage conductors, and that equal losses may be expected from weathered copper and aluminum wires of the same diameter. This investigation was suggested by previous tests (1930) made at the Ryan Laboratory, Stanford University; this earlier work indicated a temporary reduction in losses after the conductors had been cleaned.

By
W. D. WEIDLEIN
Black & Veatch
Kansas City, Mo.

IN THE INVESTIGATION described here, corona loss measurements were made on copper and aluminum wire (1) as received from the manufacturer (2) with different surface treatments and (3) after weathering. Test equipment was arranged as shown in Fig. 1 and was similar to the set-up used in the previous tests made in the spring of 1930 at the Ryan Laboratory, Stanford University. Test specimens consisted of 50-ft. lengths of No. 2 B&S gage solid conductors, supported 8 ft. 6 in. from the ground. The sag at the middle of the specimen was less than 2 in. in all cases with clearance in all other directions greater than 15 ft. In some of the tests, specimens were coated with different materials. The maximum increase in specimen diameter resulting from such treatment, however, was only 0.001 in., which would cause but very little variation of corona losses.

Insulator loss on the outer end is included in all results, but is negligible in amount; for comparative results this insulator loss does not enter in, since it was present in all tests. Insulators at the wattmeter end of the specimen were shielded so that their losses would not enter into the wattmeter reading. All tests were made within the laboratory and under as nearly similar conditions of temperature, humidity, and barometric pressure as possible.

In all tests after the specimen had been treated, the procedure followed was first to build up the specimen voltage to 100 kv. The loss at this voltage then was read, after which similar readings were taken for sucessively lower potentials at from 5-kv. to 2.5-kv. intervals, depending upon the rate of change in loss.

A comparison of losses from aluminum and copper conductors is shown in Fig. 2. The shape and shift of the curves between values of from 72.5 to 80 kv. should be noted. Joffe's theory that the resistance of a polarized layer decreases when the e.m.f. produced by polarization due to space charge exceeds 2,000 volts, ("The Physics of Crystals") is a very plausible explanation of this action. No doubt high loss from the copper conductor as received from the manufacturer is due to residue left from the "pickling" process or from drawing.

In Fig. 4 the first run (curve a-D) was made on a conductor coated with a thick film of linseed oil brushed on and dried. This wire then was cleaned and wiped once over its surface with a cloth soaked in linseed oil. A complete film was not formed, which accounts for the weathering and higher losses after drying. Curve 3-D gives the loss after wiping a second film onto the wire, and shows a decrease in losses at potentials near 75 kv. Apparently there may be some justification for the theory that with a complete thin film covering, ionizing velocities of electrons cannot be attained within the film because of an insufficient ionizing potential fall. Space charge then increases to a point where its leakage resistance starts to decrease, thus permitting a greater potential fall throughout the adjacent air and causing a sharper rise in corona loss.

In Fig. 6 curves are shown for copper and aluminum conductors, cleaned, and then suspended open to weather for about one month. These indicate equal losses for the two materials over the range tested.

Curve 3-F of Fig. 7 gives the results of a test made on a copper conductor coated with a smooth film of copper oxide formed by heating. While at 21 kv. corona was observed around this wire, no streamers formed over the range of voltage tested up to 150 kv. r.m.s. Other curves of Fig. 7 show the losses from a conductor after being heated in acetylene gas. Upon removal from the gas a granular deposit of carbon covered the conductor; the losses were as plotted in curve 1-N. After this carbon was rubbed off the losses were as plotted in curve 2-N. An interesting point in this connection was that carbon had been deposited to a depth of 1/16 in. into the conductor.

CONCLUSIONS

1. Thin films decrease corona loss.

Thin coatings of certain materials are effective in decreasing corona loss from high voltage conductors, whereas thicker films will increase such loss. Such a film may be the polished surface of a metal itself, or the formation of a film by materials which flow readily and solidify with a glaze or a crystalline surface.

2. Same losses for weathered copper and aluminum.

Corona losses from copper and aluminum conductors are practically equal after weathering, providing any detrimental effects remaining after drawing have been eliminated.

3. Favorable corona loss reduction indicated.

Favorable results in the reduction of corona loss are illustrated by the shape and shift of the curves in some cases. This conclusion is supported in several tests by deviation of the curves to the right from a straight line from high to low values of loss, and at voltages of from 72.5 to 80 kv. for the size of conductor used in these tests.

Based upon "Corona Energy Loss" (No. 31-139) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., Oct. 22-24, 1931.

Abstracts

Of Papers Presented at the Kansas City District Meeting

INTERPRETIVE abstracts of all papers presented at the A.I.E.E. Kansas City District meeting (October 22-24, 1931) are presented herewith, excepting only those papers already published in this or preceding issues of ELECTRICAL ENGINEERING. Members vitally interested and wishing to obtain immediately pamphlet copies of any of these papers are requested to use the order form appearing on p. 920 of this issue. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

Electric Arc Welding in Building Constuction

By
P. N. Vinther[1]

ELECTRICAL ENGINEERING for October 1931, p. 785-7, contained an article based upon this paper. (A.I.E.E. Paper No. 31M8)

Effect of Wave Form on Operation of Induction Relays

By
P. H. Robinson[2]

INDUCTION type relays will of course operate at their intended current values and time settings only when the shape of the current wave applied during a fault is similar to that of the test wave. The shape of the current wave in the relay during fault is dependent upon the wave form of the fault currents and voltages, and the characteristics of current transformers and secondary circuits.

Although protective relays previously have been applied upon the basis that the wave shapes throughout were sinusoidal, and that the speed of operation of relays under test and under actual system faults for similar conditions were the same, the complexity of relay problems recently encountered requires a more careful consideration of wave form.

A detailed study indicates that the wave form of fault currents need be considered only in special cases such as the application of high-speed relays. However, even with ordinary-speed relays, current transformers may produce distortion of the secondary current during fault, and the use of such devices as auto-transformers, testing transformers and phantom loads in the relay test circuits often result in extreme distortion. In general, distortion of the current wave results in slower relay operation.

Circuits for secondary tests should be so proportioned as to give a current wave as near a sine form as practical. Air core inductance coils are very effective in correcting distorted wave forms arising from the characteristics of the test circuit. Primary test circuits having carefully selected equipment is of great value in obtaining over-all tests of current transformers, secondary connections and relays. (A.I.E.E. Paper No. 31M15)

Calculating Load Division in Distribution Systems

By
C. T. Almquist[4]

A COMPARATIVELY simple and convenient method is available for solving the division of current in the various sections of an electrical network and obtaining the voltages at the different load points. The method consists essentially of the application of Kirchoff's laws to the solution of a network, the departure from the usual procedure being that instead of solving a number of simultaneous equations, the problem is handled in steps by the superposition of currents. The idea of a circulatory current is introduced when any change in the system is made by a closure between two points in the existing system.

While the method outlined is a step by step method, each step in the solution is of value in that it indicates the results obtaining for the different possible conditions of operation of the system. The application of the method is to the loop and network circuits encountered in power distribution. By its use relatively simple network circuits may be solved without the use of a calculating board. (A.I.E.E. Paper No. 31M9)

Overvoltage on Transmission Systems Caused by Dropping Load

By
E. J. Burnham[5]

THE INCREASE in voltage resulting from total or partial loss of load is especially undesirable on waterwheel driven generators because of their regulation characteristics and the fact that they are frequently connected to long lengths of high tension transmission line. The charging current of such lines results in a further increase in voltage. Although various types of relays have been used to trip the generator on the occurrence of excessive voltage or speed, a more desirable method of limiting the voltage is by the use of generator voltage regulator acting in the generator or exciter field circuit.

Tests have been made on a 47,000-kva. generator making use of a newly developed generator voltage regulator with a wheatstone bridge type of main exciter field rheostat, so adujsted that the exciter voltage may, if necessary, be reduced to a slightly negative value, thus quickly reducing the generator field current and limiting the generator armature voltage. This equipment ordinarily functions to maintain the alternating voltage normal, but at the same time is constantly ready to prevent the voltage from reaching dangerous values which would overstress the insulation of generators and connected apparatus at such time as loads might be dropped on the generating unit. The use of such equipment has made it possible to design lightning arresters and protective apparatus to give better protection.

An alternative method which is less expensive and which may be applied to older machines where it is not desirable to change the exciter to a quick response type, consists of automatically inserting a block of resistance in the alternator field circuit. This method, although not giving accurate regulation, has been found effective in keeping the voltage within desired limits when load is lost. **(A.I.E.E. Paper No. 31-140)**

Backfires in Mercury Arc Rectfiers

By
J. Slepian[6]

Impulse Voltage Tests on a 4.8-Kv. Distribution Substation

By
H. W. Collins[7]
E. E. Piepho[7]
J. J. Torok[6]

DISTRIBUTION lines from ungrounded 4,800-volt substations of the Detroit Edison Company commonly have several hundred feet of three-phase underground cable between the overhead lines and the station, voltage regulators being connected between the bus and the station end of the cable. Although lightning arresters are connected at the substation bus and at the junctions of the overhead lines and entrance cables, a number of flashovers due to lightning voltage have occurred, consistently between the line terminal of the regulator and the station end of the entrance cable.

As the result of a series of impulse voltage tests, two forms of protection were found to be effective in preventing the surge voltage rising to values sufficient to break down the entrance cable or cause flashovers at the station end. Low voltage lightning arresters shunted across the regulator series windings operate in series with the bus arrester and limit the rise of voltage on the line side of the regulator to the sum of the breakdown voltages of these two sets of arresters. The second method, and the one which is more desirable because it insures a lower voltage at the substation end of the cable, is to connect lightning arresters at this point. They limit the voltage on the substation pothead and on the regulator; and, acting in combination with the arresters on the bus and at the outside end of the cable, limit the voltage in the cable to the drops across the arresters. **(A.I.E.E. Paper No. 31-133)**

Interconnection of the 25- and 60-Cycle System of the Union Electric Light & Power Co.

By
L. V. Nelson[8]
E. L. Hough[8]

FREQUENCY conversion was determined as the best means of supplying differences between the 25-cycle and 60-cycle loads and generating abilities of the Union Electric Light and Power Company system. The hydroelectric plant at Keokuk, Iowa, was developed as a 25-cycle run-of-river plant to supply the 25-cycle load in that vicinity and to transmit power to St. Louis, where the load is largely 60 cycles. Various possibilities in 25-cycle and 60-cycle steam and hydroelectric plants presented themselves but a frequency converter was decided upon as the most desirable.

After a careful study of the five types of machines available, it was decided to purchase two variable ratio synchronous induction converter sets, each capable of transmitting 20,000 kw. in either direction, with variation from normal frequency of ½ cycle in either direction on each system.

The machines are of the six-bearing horizontal type with provisions for movement of stators to permit easy maintenance or repair. A split coupling is provided between the two main machines and the starting motor and d-c. exciters are on the 60-cycle end to permit the operation of the latter as a synchronous condenser independent of the 25-cycle machine.

It has been found that the inherent ability of the machines to change load gradually with system speed changes has been of marked benefit in stabilizing the systems. The 60-cycle machines are equipped with high speed excitation systems to hold the voltage within narrow limits, and the corrective capacity in the induction units exerts a remarkable stabilizing influence on the 25-cycle voltage. **(A.I.E.E. Paper No. 31-137)**

Automatic Control for Variable Ratio Frequency Converters

By
E. K. Shively[8]
G. S. Whitlow[9]

AUTOMATIC switching equipment for the control of two 20,000-kw. frequency changer sets using the Scherbius method of load and power-factor control has been in successful operation at the Page Avenue station of the Union Electric Light and Power Company of St. Louis for almost a year.

The switching equipment is designed so that the starting, synchronizing, voltage control, loading limiting features, and protective devices are completely automatic. The performance of this equipment during all sorts of system conditions during the past year has demonstrated the feasibility of automatically controlling large frequency changer sets. The stabilizing effect of the 60-cycle high speed excitation system on the voltage during system short circuits and the accuracy and speed of the 25-cycle synchronizing operation are of special interest. Although manual synchronizing of the 25-cycle unit is difficult because of the complex character of the excitation system and the constantly changing value of slip frequency, this operation is performed automatically in a very short time and with no interchange of power between the two systems. (A.I.E.E. Paper No. 31-136)

Forecasting Population for Engineering Purposes

By
J. N. Holsen[10]

ENGINEERS and persons responsible for the management of engineering projects have a common interest in problems of forecasting population growth and market demands. The soundness of engineering projects depends upon their capacity to fulfil a real demand. Unsoundness or even failure may result from planning and designing engineering projects without regard to industrial and population trends. Similarly city planning, housing and home building projects, educational and social programs of various kinds, ordinarily should be based upon the number of people to be served at some future date and their economic and social characteristics.

Population forecasts, when carefully and intelligently made, serve a valuable purpose in helping to direct the employment of labor and capital to places or projects where they are most needed. What will most probably occur is always the first consideration in population forecasting. Sound forecasts cannot be made to rest upon a local point of view; national factors are always involved, frequently international. In boom periods it is necessary to guard against the tendency to overestimate, while the reverse is true of dull periods. Because of the fundamental influence of economic and geographic factors in determining the population growth of cities or regions, the economic survey is invaluable in determining the probable future number of people in a particular city or region, and their social and economic characteristics. Meticulous precision is impossible in making long range population forecasts, but it is both possible and practicable to obtain a valuable working knowledge of conditions in the future. (A.I.E.E. Paper No. 31-138)

Advance Planning of Long Distance Telephone Facilities

By
C. C. McFarland[11]

THE RAPID increase in the size and complexity of the toll plant during recent years has emphasized the need for careful advance planning. This involves the development of an ultimate plan which indicates the most economical and desirable toll plant arrangement some 15 years in the future.

In developing an ultimate plan, estimates of future traffic and the corresponding circuit requirements are of great importance as are likewise the classification of the various towns and exchanges into tributaries, toll centers and switching points. Several possible arrangements of plant which will provide for the estimated circuit requirements and meet the service standards at the ultimate period are studied. Judgment must be exercised in deciding on the most desirable ultimate plan, due weight being given to such factors as cost, flexibility, and protection service.

Advance planning also is necessary in connection with individual projects involving additions and extensions to the toll plant particularly for the projects involving commitments for a number of years in the future. Several feasible plans of providing the plant are studied, the ultimate being used as a guide in setting up intermediate plans. Cost studies over a period of 5 to 15 years are made to determine the most economical scheme. (A.I.E.E. P per No. 31M14)

Tape-Armored Telephone Toll Cable

By
C. W. Nystrom[10]

BURIED tape-armored cables possess several advantages over cables carried on pole lines or in underground conduit:

1. Easements for buried tape-armored cable on private rights-of-way may sometimes be obtained more cheaply than for pole lines, as the use of the land for ordinary agricultural activities is not disturbed.
2. Induced currents from paralleling power lines are appreciably less than in unarmored aerial or underground cables, due to the shielding effect of the steel tapes.
3. Cable may be laid to follow the contour of rough country and have sharp bends to avoid obstructions, while conduit must have a fairly even grade and long radius curves to permit cable being pulled through it.
4. Manholes are required at spacings of from 500 to 700 ft. if conduit is provided, while with tape-armored cables, manholes may be omitted except at loading points which normally occur at 6,000-ft. intervals.

On the other hand, as tape-armored cables are buried directly in the earth, the location and repair of troubles are generally more difficult and more expensive than for aerial cables. However, improvements in methods for maintaining buried cables should reduce such costs, and in any event the amount of trouble per cable mile may be expected to be much less than on aerial cables, because of their security from fire, storm, and bullets.

Tractors, plows, trench backfillers, and other cable laying equipment have been developed. As a result tape-armored cable can be laid at a cost only slightly greater than that of aerial cable on pole lines, and developments now under consideration promise a rather substantial reduction in the cost of buried cable. (A.I.E.E. Paper No. 31-134)

The Time Factor in Telephone Transmission

By
O. B. Blackwell[12]

FOR ORDINARY distances of telephone communication, the speed of transmission can be considered as instantaneous. The increasing use of long distances for commercial telephony, however, has introduced time problems in telephone transmission which are of considerable technical interest and difficulty. Although a number of papers have been presented on this subject, none seems to have given a general over-all picture.

In actual telephone circuits the speed of transmission is reduced from the speed of light by the impedance of the circuit, and varies considerably in different circuits. Five different types of problems in telephone communication are introduced. First, conversation may be slowed down by the time interval between the formation of a sound by the speaker and its reception by the listener. In two-way conversation this may become important as it causes a delay in reply. Second, differences in the speed of transmission of the frequencies which make up speech may produce peculiar distortions which cause considerable interference. Third, echo effects may arise from the reflection of energy at points of irregularity, particularly at the end of the circuit. These echoes have the greatest effect on the talker who may have an uneasy feeling that the distant party wishes to break in on the conversation. Fourth, the voice-operated devices which are sometimes connected in the circuit, and which overcome echoes by rendering inoperative transmission in the opposite direction, may result in a delay in transmission and introduce other serious difficulties. The fifth factor is that of fading, which although not included in this discussion may result when there is more than a single path between the sending and receiving ends of a circuit. **(A.I.E.E. Paper No. 31-135)**

Lightning Disturbances on Transmission Lines

By
D. C. Jackson, Jr.[13]
R. W. Warner[13]

MOST OF THE more important studies of lightning disturbances on transmission lines have been confined to steel tower lines of 110 kv. and above. A field investigation of the effect of lightning on 33-kv. and 66-kv. transmission lines on wood poles is now being carried on, the preliminary investigations having been completed.

Data have been compiled showing the direct lightning hits and flashovers per pole in the Mississippi and Missouri River valleys. These indicate for example that guyed poles are more subject to disturbances than unguyed poles, and that corner poles also are more frequently affected. It was found that in the case of 66-kv. lines practically two-thirds of the guyed poles were hit or flashed over, whereas only about one-half of the guyed poles on the 33-kv. lines experienced lightning troubles. The proportion of unguyed poles affected was practically the same for both voltages.

The data indicate that there is little difference between the amount of lightning trouble experienced by poles in rolling country and by those in flat river bottoms. It is stated that whether pole stands on the crest of a hill, on a slope, in a valley, or on open low land has little effect on the number of lightning disturbances. It is hoped that the continuance of this investigation will produce definite explanations of the causes of the phenomena observed. **Pamphlet copies not available.**

Corona Energy Loss

Application of Primary Distribution Fuses

By
F. E. Sanford[15]

THE FUNCTION of the primary fuse is to clear short circuits, and to minimize disturbances to the system at times of fault. Continuity of service requires that short-time overloads should not cause primary fuses to blow, whereas fire hazard requires that fuses for secondary windings operate on an overload basis. The proper application of primary fuses is dependent upon the determination of the available short-circuit current as well as the value of load current. Another factor which must be given consideration is coordination of fuse and relay time-current characteristics to insure isolation of the fault at the fuse point rather than by the main feeder switch. Minimum time of operation should be sought in the selection of fuses, both to provide maximum flexibility in relay settings and to give minimum system disturbance. The time required for a fuse to blow in the short-circuit current range is more important than at the one or five minute points.

To be consistent with the rating of other electrical equipment, fuse ratings should be based upon their continuous carrying capacity. Ratings on some other basis are likely to cause confusion, and to make an accurate comparison between different types of fuses difficult. Consistent ratings also would facilitate interchange of fuses of different types. **(A.I.E.E. Paper No. 31M10)**

The Expulsion Fuse

By J. Slepian[6]
C. L. Denault[6]

THE EXPULSION fuse is an extremely simple device used quite extensively for interrupting a-c. circuits of moderate voltage and power. In spite of its apparent simplicity and widespread use, the principles upon which it functions are not at all generally understood. Comparisons of interrupting capacities of a soapstone fuse tube and a fiber fuse tube, support the view that the expulsion fuse depends upon the gas blast produced by rapid decomposition of fuse tube material under the heat of the arc. The effectiveness of the gas blast is stated to be due to the high degree of turbulence it introduces into the confined arc space.

The voltage interrupting capacities *versus* ampere capacities for a fiber tube and for a boric acid lined tube have been obtained experimentally, and it is found that the curves for boric acid lie much higher than for fiber. The characteristics were found to depend very materially upon the number of half cycles of arcing. Also it has been found that the circuit voltage which can be interrupted rises rapidly as the size of tube is decreased.

An interesting development of the expulsion fuse is the use of flame suppressors for deionizing the issuing flame. It has been shown that by introducing means for condensing the water vapor, the boric acid lined tube may be completely closed without the development of excessive pressure. In fuse design, consideration must be given to insure that the gas generating materials which aid in arc extinction will withstand the full circuit voltage with the passage of only small current, even when heated by the arc. **(A.I.E.E. Paper No. 31-141)**

Fuse Cut-Outs—Their Design and Application for A-C. Distribution Circuits

By
E. G. Newton[16]

MANY NEW developments to meet modern requirements have been applied to the renewable expulsion-fuse and oil-fuse cut-outs for a-c. distribution systems of 15,000 volts and below. While there are several different types of fuse cut-outs, the universal design problem is the interruption of an arc formed when the current carrying element melts. Both expulsion-fuse and oil-fuse cut-outs depend for this interruption upon the gas pressure generated by the current in the arc.

Three factors, circuit voltage, load current, and fault current govern the proper selection of fuse cut-outs and fuse links to meet the different service requirements. These factors are shown to have a relationship necessitating equal consideration in order to secure safe and reliable operation. Coordination also must be secured with other apparatus on transmission and distribution systems. Investigations now being made on the effect of power factor on arc interruption may have an important bearing on the future design of fuse cut-outs. **(A.I.E.E. Paper No. 31M11)**

Of Institute and Related Activities

Thomas Alva Edison—
February 11, 1847-October 18, 1931

BRINGING to a close one of the most colorful careers in history, Thomas Alva Edison, indefatigable promoter of the incandescent electric lamp, quietly breathed his last at 3:24 a. m. October 18, 1931, almost exactly 52 years after his invention of that lamp. He died at "Glenmont" his West Orange (N. J.) home in which he has lived since 1886. Apparently convinced for some weeks that his many sided life work was at an end, he is reported as having expressed a feeling of "inadequacy" for the continuation of the tasks to which he has devoted his best efforts during his allotted span of years.

Thomas A. Edison's characteristic, clear cut signature occupies a prominent place upon the original call issued in the spring of 1884 for the organization meeting of the American Institute of Electrical Engineers. This historic document, which occupies a conspicuous place in the members' room at Institute headquarters in New York, stated that "it seems probable that the persons who are interested in electrical, scientific, educational, manufacturing, telegraphic, telephonic, and like concerns, as well as the users of electrical appliances generally, will find it to their advantage, personally and collectively, to establish, support, work for, and generally aid our proposed Society."

Edison not only was one of the organizers of the Institute, but at its first election of officers, May 13, 1884, he was elected a vice-president. Thus, while electricity surely was in its infancy, Edison was actively interested in creating an organization the objects of which were to be as they still are as stated in its Constitution "the advancement of the theory and the practise of electrical engineering and of the allied arts and sciences, and the maintenance of a high professional standing among its members."

Edison Medal Established

In recognition of the inspiration to workers in the fields of engineering and science as provided by Edison's spirit and character in his life work, the Edison Medal was established in 1904 by an organization of associates and friends of Edison, "for the purpose of appropriately recounting and celebrating the achievements of a quarter of a century in the art of electric lighting with which the name of Thomas Alva Edison is imperishably identified. The A.I.E.E., in response to an invitation, undertook the responsibility of making the awards of this gold medal which its sponsors designated should "during the centuries to come serve as an honorable incentive to scientists, engineers, and artisans, to maintain by their works the high standard of accomplishment set by the illustrious man whose name and features shall live while human intelligence continues to inhabit the world." The first award of this medal was made to Dr. Elihu Thomson in 1909; subsequently to: Frank J. Sprague, George Westinghouse, William Stanley, Charles F. Brush, Alexander Graham Bell, Nikola Tesla, John J. Carty, Benjamin G. Lamme, W. L. R. Emmet, Michael I. Pupin, Cummings C. Chesney, Robert A. Millikan, John W. Lieb, John W. Howell, Harris J. Ryan, William D. Coolidge, Frank B. Jewett, Charles F. Scott, Frank Conrad.

In June 1928 the A.I.E.E. was privileged to give further recognition to Edison's services and achievements. The Constitution provides that Honorary Members may be chosen, upon the unanimous vote of every member of the board of directors, from among those who have rendered acknowledged eminent service to electrical engineering. Prior to June 1928 the very few distinguished persons thus elected all were from foreign countries, but at that time Edison's name headed the list of five outstanding American engineers unanimously endorsed by the directors.

The Genius of Edison

In his biography "Edison As I Know Him," Mr. Ford described Edison as "a genius but not in the sense that his inventions and discoveries have been revealed to him in sudden flashes. If he

Two "wizards" at work—Edison and Steinmetz examining porcelain insulators fractured by artificial lightning were that, he would not have his present tremendous importance, for the lessons of his life would not have universal application. As it is, his methods can be used by any one; and the fact that they are being used by so many is one of the reasons for our great industrial progress. The man stands as a demonstration of what concentration and intelligence can accomplish."

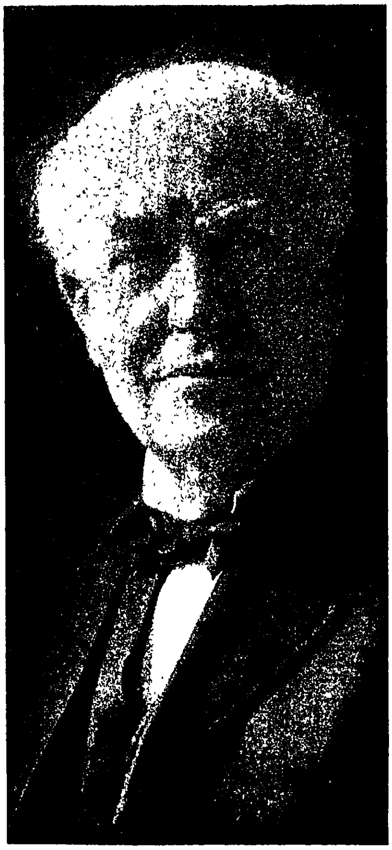
One of his earlier interests and certainly the one most consistently and earnestly pursued by Edison through and in spite of seemingly insurmountable difficulties, was the development and improvement of the incandescent electric lamp and a parallel system of distribution which would make electric light as readily accessible to the individual consumer as the older established utility systems which provided water and gas service.

Other experimenters had been busy on the problems of both the arc light and the incandescent light, the former of which already had reached a successful commercial stage. Self-exciting generators for both continuous and alternating current had been developed, and as early as 1859 Prof. Moses G. Farmer had conducted successful experiments with incandescent lights comprising a metal filament enclosed in a glass globe from which air had been partially exhausted. It had been predicted by Professor Farmer that the success of the incandescent lamp would hinge upon successful accomplishment of the necessary vacuum. Edison, after contemplating the limitations of the arc light, disregarded contrary current opinion and in the face of ridicule and violent criticism turned his tireless, bold, and imaginative effort toward the development of a commercially successful incandescent electric lamp. Thus it was that on October 21, 1879, Edison achieved his first successful incandescent carbon lamp, the tiny foundation upon which has been built a five billion dollar industry.

THE THREE WIRE SYSTEM

With the fundamental problem of the incandescent lamp settled, came the demand for improved types of dynamo-electric machines and the development and improvement of commercial distribution systems for electric energy. To meet these demands Edison's tireless work of 1879-80 laid the foundation and unerringly pointed the path which the successful commercial development of electric lighting must follow. It is of interest to note here in passing that Edison was unalterably opposed to the evolution and development of the alternating current system.

The Edison three wire system of distribution, really a multiple-series grouping of lamps supplied by dynamos connected in series with a grounded balance wire between the dynamo connection points and the lamp groups, was as fundamental to the advance of electric lighting as the development of the lamp. As with the lamp itself, the three wire system was invented independently in England, but again it was Edison's driving energy and deep insight that underlay commercial success. The famous Pearl Street station in New York City, the first central electric generating station in the western hemisphere, followed almost immediately upon the completion of a similar station at Holborn Viaduct in London where two 1,000-light Edison generators were placed in service in 1882.



Thomas Alva Edison—

"It is given to few men of any age, nation or calling to become the benefactor of all humanity. That distinction came abundantly to Thomas Alva Edison, whose death in his eighty-fifth year has ended a life of courage and outstanding achievement. His lifelong search for truth, fructifying in more than a thousand inventions, made him the greatest inventor our nation has produced, and revolutionized civilization itself. He multiplied light and dissolved darkness; he added to the whole wealth of nations. He was great not only in his scientific creative instinct and insight, but did more than any other American to place invention on an organized basis of the utilization of raw materials of pure science and discovery. He was a rare genius. He has been a precious asset to the whole world.

"Every American owes a personal debt to him. It is not only debt for great benefactions which he has brought to every American, but also debt for the honor he brought to our country. By his own genius and effort he rose from a newsboy and telegrapher to the position of leadership amongst men. His life has been a constant stimulant to confidence that our institutions hold open the door of opportunity to those who would enter. He possessed a modesty, kindliness, a stanchness of character rare among men.

"His death leaves thousands bereft of a friend, the nation bereft of one of its notable citizens and the world bereft of one of its greatest benefactors. I mourn his passing as a personal friend over a quarter of a century."—

HERBERT HOOVER

EARLY INVENTIONS

Legitimately hailed as the father of commercially successful electric lighting as it now is known throughout the world, Edison also was the developer and inventor of other ideas, methods, and apparatus entirely too numerous to mention. The record of his inventions at the United States Patent Office shows that since 1868 more than 1,200 patents have been granted to Edison covering an astoundingly wide range of subjects. Prior to his successful development of the incandescent electric lamp in 1879, Edison had invented the phonograph (1877); completed basic inventions in automatic telegraph systems, multiplex telegraph apparatus, and a carbon telephone transmitter which was used by Doctor Bell in the commercial application of his own telephone instrument (1871-77); contributed to the development of the successful working model of a typewriter (1871); contributed inventions fundamental to the ultimate successful development of the stock ticker (1870). His first recorded invention (1868) was his electrochemical vote recorder which he patented with the idea of having it installed in the houses of Congress. As a commercial venture, however, this first recorded patent was a complete failure, the result of which was to cause Edison to devote his subsequent efforts to the development of apparatus for which he could see a reasonably sure market as a reward for the achievement.

THE PHONOGRAPH

The invention of the basic idea of the phonograph and the development of related materials and apparatus is credited without even the shadow of a competitive claim to the ever-questing inventive brain of Mr. Edison. Imbued with the idea that he could make sound waves record themselves mechanically to be reproduced subsequently at pleasure, Edison is credited with having developed his phonograph within one week after having first set to work at it. This invention is regarded as illustrating Edison's mastery of many fields. It is evident that his previous work in the development of a commercially successful telephone transmitter provided him with a background of experience and experiments which enabled him to make such startling developments with his phonograph idea.

THE "EDISON EFFECT"

In 1883 the phenomena later described as the "Edison Effect" was noted by Edison and discussed at some length by contemporary electrical engineers. In fact, at the first meeting of the Institute held at Philadelphia, Pa., in October 1884, a paper was presented by Dr. Edward J. Houston, "Notes on Phenomena in Incandescent Lamps," and this paper may be found as the first paper in Vol. 1 of the TRANSACTIONS of the Institute. The discovery of this "Edison Effect" was the fundamental root system upon which was based and from which grew the great radio industry of today, including the thermionic tubes that have been developed for purely industrial purposes. This important fundamental discovery, stumbled upon by the noted inventor, lay dormant for more than 30 years while its discoverer devoted his energy to other and more obvious projects. As was typical with the more or less incidental discoveries made by Edison, he no sooner had evolved the principle than he discarded it when it failed to bear fruit.

Edison's first glimpse of this all-important principle underlying the thermionic tube of today was described in an article in *The Atlantic Monthly* for December 1930:

"While working on his incandescent lamp in 1883 Mr. Edison noticed that when he heated the filament to a certain temperature a blue glow appeared between the legs. Was this electricity flowing through rarefied air? If so, it seemed strange that the current should take this more resistant path in preference to the easier channel provided by the loop filament itself. To satisfy his curiosity the inventor inserted a second element into the bulb—a wire. He connected the wire to the positive terminal of the lamp and found that a weak current did flow from the hot filament, but, curiously, when the connection was changed to the negative terminal, no current flowed.

"Edison noted the experiment in his notebook and turned from this fascinating side issue back to his main job of developing the incandescent lamp. . . .

"It was not until 1905 that this flow of power in a vacuum was harnessed to do useful work."

Thomas A. Edison as Seen by Some Institute Leaders

LEWIS B. STILLWELL—Edison's greatest contribution to mankind was the incandescent lamp and the central station for supplying electricity through feeders and mains to adjacent territory. Next to this achievement, his greatest contribution, perhaps, has been the stimulus of his example. His simplicity of life, his untiring industry, and his infinite patience in overcoming difficulties have been an inspiration to countless workers.

GANO DUNN—If for no other reason, Edison will be immortal as the first man to record and reproduce human speech. His contributions to electrical generation, distribution, and illumination, without including the invention of the phonograph, place his name among the great ones of the earth. In his death I lose an inspiration and a kind personal friend from boyhood, whose youth and vitality of personality blazed to the last as a light to the world.

HARRIS J. RYAN—Mr. Edison was much more than the inventor of the incandescent lamp, the phonograph, and the motion picture. He will rank forever with the greatest practical explorers of the feasibles and permissibles that determine human welfare and happiness on this earth. He did a lion's share of the work that will forever distinguish the transition from the 19th to the 20th century. He was a philosopher who, by his example, taught millions the glory of unremitting toil.

A. E. KENNELLY—We of the electrical engineering fraternity deeply regret the loss of our great American inventor, Thomas A. Edison. As his principal electrical assistant from 1887 to 1894 it was my privilege to work with him daily. His great energy and enthusiasm made those years very happy and memorable to me. As a chief, he was always inspiring, encouraging, and sympathetic, and all of us at the laboratory revered and loved him. We forgot obstacles and even the passage of time, in our work under the direction of his grand personality.

M. I. PUPIN—Edison's greatest contribution to the comforts of mankind undoubtedly is the incandescent electric lighting system. Edison always loved to reminisce about his wonderful experiences in the course of developing the incandescent filament, and no biography will be complete without these reminiscences. This development work, crossed at every step by almost insurmountable difficulties, illustrates better than anything else Edison's genius. He was a great inventor, but he was also a great personality, the unique combination of the two will never be forgotten.

C. E. SKINNER—The name of Thomas A. Edison and the development of the electrical industry are and will be inseparable. His contributions to the electrical art, as well as to many other subjects, have been continuous for more than fifty years. His research has been characterized by tireless energy and a mind which led him to try methods and materials for the attaining of his objectives which perhaps would never be thought of by the average research worker. In his passing the electrical industry loses its greatest pioneer and the world an unique and outstanding figure.

MOTION PICTURE DEVELOPMENT

Work done by Edison in 1889-90 and 1891, resulted in his achieving basic inventions in the field of motion picture recording and projecting. This work was followed by additional developments during the ensuing 35 years or more which contributed toward the development of successful motion picture apparatus. It is interesting to note in this connection that although Edison made inventive contributions of the greatest importance in the field of the phonograph and the photographic film for the recording and reproduction of sound waves, and also in the field of motion picture recording and projecting, it is reported authentically that Edison was convinced even up to his last active days that the combination of sight and sound in the form of the modern talking motion picture would prove to be but a passing public fancy and, therefore, not attractive enough to him to cause him to devote serious energy to it.

EDISON IN CHEMISTRY

Edison had a strong liking for experimental work in the field of chemistry, an interest which periodically had burst into flame during his many years of development efforts, but which always had been pushed into the background to keep the way clear for his other major activities. However, the participation of the United States in the World War and Edison's immediate devotion of effort to government service gave him the opportunity to "putter" with chemicals, something which for several years he had been hoping for privately. Faced with a direct need for carbolic acid, aniline dyes, and other chemicals in this country, normal supplies of which had been interrupted by war conditions, Edison took great pleasure in the fact that "within sixty days after we decided to make carbolic acid we had a plant built and were making it."

As head of the United States Navy Consulting Board (1915) and life head of the United States Naval Recruiting Board (1917) Edison devoted his seemingly tireless energy to the development of vitally important new war materials and equipment. After the war Edison devoted much attention to the project of developing a domestic rubber supply and experimented with synthetic products. As usual, however, this was just one of his many and widely varied activities.

Space limitations prohibit the reproduction here of anything like a complete life story of Mr. Edison's many sided activities. Those interested in the details of the life of this inspired world character are referred to the biographies "Edison As I Know Him" by Henry Ford, "Edison, the Man and His Work," by Geo. F. Bryan, and the biography prepared by William H. Meadowcroft, historian for the Edison Pioneers, and lifelong associate of Mr. Edison.

Turning from Edison the inventor to Edison the man, one finds a simple, direct stable philosophy of living given such a dynamic force by the example of his devotion to his work that its stimulating and inspiring effect will outlive him by generations. Students in the fields of applied science have had in him an ideal by which to guide their ambitions; by his infectious enthusiasm and vitality of personality men of science and industry have been encouraged to redoubled efforts in the face of devastating adversities. By his example he demonstrated the glory of unremitting toil directed toward knowing things and doing things that are of service to humanity. Thus, recognition is due him by Humanity as well as by Industry. The fruits of Edison's vigor, indomitable courage, and simple, effective philosophy of hard work beyond doubt were made available to the world for an unusually extended period through the untiring ministrations of his wife, Mina Miller Edison. Thus also is a debt of gratitude owed to her.

November 15 Last Date For Suggesting Nominations

Actions specified in the Institute's constitution and by-laws relative to the organization of a national nominating committee are being taken, and the meeting of the national nominating committee for the nomination of officers to be voted upon at the election in the Spring of 1932 will be held between November 15 and December 15. All suggestions for the consideration of the national nominating committee must be received by the secretary of the committee at Institute headquarters, New York, not later than November 15.

Secret Telegraph Messages.—A new and very successful means for telegraphic and wireless transmission in secret was described recently before the Academy of Sciences by General Gustave Ferrie of the French Institute. The new method makes use of devices in a French inventor's system of sending orthographic texts by means of cylinders moving at variable speeds and synchronized according to a prearranged plan between the sending and receiving stations. Each message bears the reproduction of the signature of the sender. It can be concealed further from any outside station by means of a simultaneous and more powerful text which has no connection with the secret message. General Ferrie stated that this system was expected to prove valuable for military and diplomatic communications.—*Telegraph and Telephone Age.*

In Memory of Thomas Alva Edison

The physical life of Thomas Alva Edison, world benefactor, ended on Sunday, October 18, 1931. The spiritual benefits of his contributions to humanity continue to live.

His genius, vision, patience, persistence, industry, and widely diversified talent, which brought to fruition many of his conceptions, have contributed greatly to the comfort, convenience, and happiness of mankind; his achievements constitute a great incentive and inspiration to those who follow.

In particular, his invention of the incandescent electric lamp and his conception, more than 50 years ago, of the combination of a central generating station with a suitable distributing system for electric energy firmly establish him as the founder of the electric lighting industry of the world.

He was the outstanding world leader in the group of inventors, scientists and engineers, whose achievements in technology have produced great social and economic benefits including the employment, in useful occupations throughout the civilized world, of tens of thousands of men and women.

He was respected and admired by his associates who cherish their memory of his ability, simplicity, and other personal characteristics.

Mr. Edison was, in 1884, one of the signers of the call for the organization of the American Institute of Electrical Engineers, and he was elected vice-president at the first election of officers; later he was elected an Honorary Member. His achievements caused a group of his associates and friends to establish the Edison Medal, which now is awarded annually by this Institute.

The board of directors of the A.I.E.E. hereby records in its minutes this appreciation of the great debt which the world, and electrical engineers in particular, owe to his memory, and directs that a copy of this minute be sent to his family.—From the minutes of the regular meeting of the board of directors, held at Kansas City, Mo., October 23, 1931.

Electric Furnaces Improved for Iron and Steel Plants

During the past two decades electric furnaces for melting and refining in the iron and steel industry have shown noteworthy progress. In a paper presented by W. E. Moore, metallurgical engineer of the Pittsburgh (Pa.) Electric Furnace Corporation, before the sixtieth general meeting of the Electrochemical Society held September 2-5, 1931, at Salt Lake City, Utah, it was stated that the electric arc type of furnace has increased sixty-five times in number, five times in maximum size per heat and ten times in maximum daily capacity. Power consumption was said to have been decreased from an approximate average of 700 to about 500 kw-hr. per unit ton output with a corresponding decrease in carbon electrode consumption from an approximate average of 35 to about 11 or 12 lb. per unit ton output. It is stated that by reason of these improvements, as well as by reason of the more rapid type of operation and lower maintenance, refractory, and slag costs, the total conversion cost has been reduced accordingly.

In comparing production figures it is stated that in 1910 ten electric steel furnaces were in operation in the United States producing 52,141 gross tons of electric steel during that year. In 1930 approximately 650 electric furnaces were in operation on iron and steel properties in the United States, giving an average annual output of more than 1,000,000 tons gross, of which approximately one-third was ingot and two-thirds steel and iron castings. It was stated further that approximately one-third of all steel for castings now is melted electrically.

Noble Prize Awarded by A.S.C.E.

Announcement just has been made of the award of the 1931 Alfred Noble Prize to Prof. C. T. Eddy, of the Michigan College of Mining and Technology, Houghton, Mich. This is the first award of this prize, which is accompanied by $500 in cash, and which should be of particular interest to all the younger members of the engineering profession.

The older members of that calling well remember Alfred Noble who, during a professional career of more than 50 years ending in 1914, participated in many public works for which the citizens of the United States still remain his debtors, although his characteristic modesty prevented his name being known in connection with them. His experience was of value in connection with the location and construction of the Panama Canal. He was one of the engineers who built the Pennsylvania (R. R.) Terminal in New York City. The project of bringing water from the Catskill mountains to the City of New York was guided in part by his knowledge and advice. In addition to his technical achievements, Mr. Noble took a great interest in the welfare of his colleagues, especially in the younger men who were just starting out in the engineering profession.

Very soon after his death, the American Society of Civil Engineers, of which he had been president in 1903, appointed a committee to collect funds for a memorial to perpetuate his memory. This finally has taken shape in a fund the income of which is to be used for an annual award of $500 to a younger engineer, who might thereby be encouraged in his chosen work and be led to emulate Alfred Noble, though he had never had the privilege of knowing him.

The prize is awarded upon the recommendation of a committee consisting of representatives from the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the Western Society of Engineers. Award is made for a technical paper of particular merit written by a member of one of these societies, and accepted for publication before the author has reached the age of 30 years. Professor Eddy's paper, on "Arsenic Elimination in the Reverberatory Refining of Native Copper," to be published in the *Transactions* of the American Institute of Mining and Metallurgical Engineers, of which he is a member, was adjudged worthy of the first award. The presentation will take place at a future meeting of the A.I.M.E.; and the prize will be given to Professor Eddy by a representative of the A.S.C.E., trustee of the fund.

New York Power Group to Discuss Protection

The A.I.E.E. New York Section Power Group will hold a meeting devoted to power system protection on the evening of November 24, in Room 1, fifth floor, Engineering Societies Building, 33 West 39th Street, New York, N. Y. Addresses will be delivered by H. D. Braley, assistant engineer, New York Edison Company, and by H. P. Sleeper, engineer, Public Service Electric and Gas Company.

Mr. Braley will emphasize the necessity of planning protection in close conjunction with system design, both present and future; Mr. Sleeper will review pertinent operating experiences of his company with various types of system protection. Conforming to the established practise of the New York Section Groups, this meeting will be called promptly at 7:30 p. m. and will adjourn at 9:30 p. m. Discussion is open to all.

Administrative Engineering.—A new course in engineering leading to the degree of Bachelor of Science in administrative engineering has been included in the curriculum of Cornell University, Ithaca, N. Y., coincident with the academic year 1931-32. It is stated that this course has been instituted in answer to demands from industry for engineers having the training necessary to qualify for administrative responsibilities in engineering and industrial enterprises. The new course requires four years for completion and includes ten subjects of a non-engineering nature.

Leading Educator Dies

S. W. STRATTON

Dr. Samuel Wesley Stratton (A'04-F'24) chairman of the Massachusetts Institute of Technology Corporation and former president of M.I.T., died suddenly at his home October 18, 1931. Doctor Stratton was born July 18, 1862, at Litchfield, Ill., and was graduated from the University of Illinois in 1884 with the degree of bachelor of science in mechanical engineering. Later he received honorary degrees from the University of Illinois, Rensselaer Polytechnic Institute, University of Pittsburgh, Cambridge University (England), Yale University, and Harvard University. During the period of 1885 to 1892 he was instructor in mathematics, assistant professor, and later professor of physics and electrical engineering at the University of Illinois, organizing the department of electrical engineering at that institution. The following nine years he was successively assistant professor, associate professor and professor of physics at the University of Chicago, in 1901 becoming director of the National Bureau of Standards at Washington, D. C. Continuously from that time until 1922 he was director of this bureau, being responsible for its organization and development into a great institution, which not only is devoted to the scientific determination of weights and measurements, but has become a great physical laboratory cooperating with American industry and commerce in the solution of many problems of enormous value. Under Doctor Stratton's direction this bureau grew from a small organization of twenty-four employees in temporary quarters near the Capital to an institution with 900 workers and fourteen permanent buildings. In 1923 he resigned this position to become president of Massachusetts Institute of Technology, Cambridge, Mass., in order that he might adapt the practical and efficient methods of the bureau to what was already a leading technical school. In 1930 he was appointed chairman of the Massachusetts Institute of Technology Corporation executive board, calling Dr. Karl T. Compton, head of the department of physics at Princeton University, to be president. France made him a chevalier of the Legion of Honor in 1909, and an officer in 1928; he had received the Elliott Cresson Medal of the Franklin Institute, and the Welfare Medal of the National Academy of Sciences. He belonged to many clubs and organizations, among which were the American Society of Mechanical Engineers, the American Physical Society, the American Philosophical Society, the National Academy of Sciences, and the American Association for the Advancement of Science. He was also a member of the interdepartmental board of the Council of National Defense, and the National Advisory Committee for Aeronautics; three years ago he accepted the invitation of Secretary Wilbur to serve on the navy board named to study safety devices for submarines.

Winter Convention Plans are Announced

With the technical program for the 1932 winter convention of the Institute already essentially completed, activities and preparations for the coming event now are in full swing with the appointment by President Skinner of the general convention committee. Winter convention activities are scheduled for Jan. 25-29, 1932, with convention headquarters at the Engineering Societies Building, 33 West 39th Street, New York, N. Y.

As members of the general convention committee, Doctor Skinner has appointed the following: *chairman,* E. B. Meyer (F'27) chairman publication committee; O. H. Caldwell (M'22) chairman New York Section; H. P. Charlesworth (F'28) vice-president; Harold C. Dean (F'30) secretary New York Section; W. H. Harrison (F'31) chairman meetings and papers committee; C. R. Jones (F'31) secretary, New York City District; G. L. Knight (F'17) A.I.E.E. representative on Board of Trustees, United Engg. Trustees, Inc.; C. E. Stephens (M'22) chairman finance committee; R. H. Tapscott (F'29) chairman headquarters committee.

In planning the technical program special efforts are being made to cover the art completely during the year. Hence, on the winter convention program there surely will be several sessions on subjects which have not been presented at this annual affair during the past few years. Indications point toward the presentation of very large number of papers, some of which will be presented from the manuscript without publication, and without distribution of an advance copy. Three sessions tentatively scheduled accommodate symposiums: (1) distribution circuit lightning protection, (2) system stability, (3) time and time services. The symposium on system stability promises to be of wide general interest. It is sponsored by the joint subcommittee on interconnections which is comprised of members of the committees on power generation, power transmission and distribution, and protective devices. Other subjects tentatively under consideration for sessions are: instruments and measurements, research and general circuit theory, protective devices, electrical machinery, electric welding, communication, electrochemistry and electrometallurgy, transportation, and several selected subjects.

These plans should leave nothing to be desired from a standpoint of technical interests. Plans for the social features, entertainment and inspection trips will not be left undone and these will be announced at a later date.

Letters to the Editor

Corona and Line Surges

To the Editor:

Dr. H. H. Skilling's article "Corona and Line Surges," which appeared in the October 1931 issue of ELECTRICAL ENGINEERING, prompts me to submit a comparison between the following four different formulas for the attenuation of traveling waves:

1. Simple exponential attenuation, which is exact for the ideal transmission line in which the line "constants" R, L, G, C are true constants.
2. The Foust and Menger empirical formula, which appeared in W. W. Lewis's 1928 A.I.E.E. paper "Surge Voltage Investigation of Transmission Lines."
3. The Skilling formula, described in his article.
4. A formula based on the assumption that the corona loss for traveling waves follows the quadratic law, the derivation of which is given as an appendix to these comments.

Referring to Fig. 1, in which these four formulas have been plotted so as to pass through a common point at 50 per cent of the initial voltage of the surge, it may be seen that there are three principal regions involved:

Region I—from the initial voltage of $E = 2{,}000$ kv. to the 50 per cent voltage point of 1,000 kv.

Region II—from $e = 1{,}000$ kv. to the critical corona voltage $e_0 = 500$ kv.

Region III—below the critical corona voltage $e_0 = 500$ kv.

In region I, the Foust and Menger formula agrees almost perfectly with the quadratic formula, and Skilling's formula agrees equally well with the exponential law. The difference between these two pairs is not great, and of little practical importance. In this region of greatest interest all four formulas are of practically equal accuracy, and therefore the formula will be used which is the most convenient. The Foust and Menger formula is the most simple for estimating the attenuation, but the exponential formula is easier to operate mathematically.

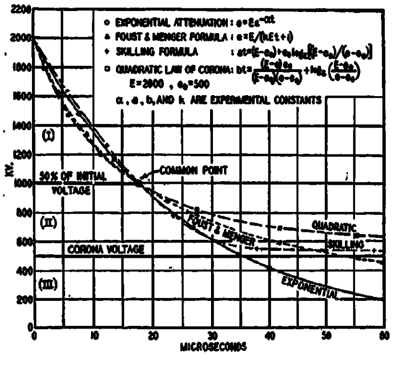


Fig. 1. Comparison of formulas for attenuation of traveling waves

In region II the Foust and Menger formula parts company with the quadratic formula, but the Skilling formula and exponential law continue to agree until the critical corona voltage is neared, when the Skilling formula abruptly flattens out while the exponential crosses to region III.

Both the Skilling and the quadratic formulas are asymptotic to the critical corona voltage, and therefore do not appear in region III. The Foust and Menger and the exponential formulas enter region II, but at widely different points and diverge considerably.

While the exponential, Skilling, and quadratic formulas, appear on the surface to have been derived by a rational process, it should be noticed that all three of them are based upon the assumption that the current and voltage waves are exact replicas of each other; in other words, the distortion is ignored. Moreover, the experimental constants α, a, b have to be determined from tests on the transmission line in question and under the actual conditions that are to prevail. Thus in this respect they are no better off than the Foust and Menger formula. The very abrupt flattening of the Skilling formula as the critical corona voltage is approached is not always evidenced by experimental data.

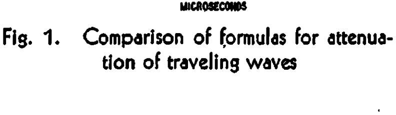

Fig. 2. A typical traveling wave f4

MATHEMATICAL EXAMPLE

Consider a traveling wave $e = f(x - vt)$ of length D, (Fig. 2) and its companion current wave i, and suppose that these two waves are related by the surge impedance:

$$e = Z\,i = \sqrt{\frac{L}{C}}\,i \tag{1}$$

At time t the toe of the wave is at $x = vt$ from the origin, and the total stored energy of the wave is

$$W = \frac{C}{2}\int_{(vt-D)}^{vt} e^2\,dx + \frac{L}{2}\int_{(vt-D)}^{vt} i^2\,ds$$

$$= C\int_{(vt-D)}^{vt} f^2(x - vt)\,dx \tag{2}$$

The rate at which the energy content is changing with respect to t is

$$\frac{dW}{dt} = C\int_{(vt-D)}^{vt} \frac{\partial}{\partial t} f^2(x - vt)\,.\,dx$$

$$+ C\,v\,f^2(vt - vt) - C\,v\,f^2(vt - D - vt)$$

$$= C\int_{(vt-D)}^{vt} \frac{\partial}{\partial t} f^2(x - vt)\,.\,dx$$

$$= C\int_{(vt-D)}^{vt} \frac{\partial e^2}{\partial t}\,dx \tag{3}$$

because $f(0) = 0$ and $f(-D) = 0$

Now if the rate of energy dissipation due to the line losses is a function of the voltage $\phi(e)$, then the total rate of energy loss for the entire wave is

$$\int_{(vt-D)}^{vt} \phi(e)\,.\,dx \tag{4}$$

Equating (3) and (4) and discarding the integrals

$$C\frac{\partial e^2}{\partial t} = -\phi(e) \tag{5}$$

subject to the initial conditions

$$e = E(x) \text{ at } t = 0 \tag{6}$$

The solution of (5) thus defines the wave at any instant t. By way of illustration, three special cases will be considered.

CASE I—Ideal Transmission Line.—Such a line is characterized by four line constants R, L, C, G and if eq. 1 holds, the rate of energy loss is

$$\phi(e) = R\,i + G\,e^2 = R\frac{C}{L}e^2 + G\,e^2$$

$$= \left(\frac{RC + LG}{L}\right)e^2 \tag{7}$$

Substituting (7) in (5) and using (6) this results in

$$e = E\,\epsilon^{-\alpha t} \text{ where } \alpha = \frac{1}{2}\left(\frac{R}{L} + \frac{G}{C}\right) \tag{9}$$

CASE II—The Skilling Formula.—If the loss is assumed to vary as the excess voltage above the critical corona voltage e_0, then

$$\phi(e) = -k(e - e_0) \tag{10}$$

and (5) and (6) give

$$\frac{k}{2C}t = a\,t = (E - e) + e_0\log\left(\frac{E - e_0}{e - e_0}\right). \tag{11}$$

CASE III—The Quadratic Formula.—If the loss is assumed to vary as the square of the excess voltage above the critical corona voltage, then

$$\phi(e) = -K(e - e_0)^2 \qquad (12)$$

Then by (5) and (6)

$$\frac{Kt}{2C} = \frac{(E - e)\,e_0}{(E - e_0)\,(e - e_0)} + \log\frac{(E - e_0)}{(E - e_0)} \qquad (13)$$

I have in the past devoted a considerable part of my time to the study of traveling waves, and feel that the attenuation of surges is the most important thing left to be found out about traveling waves. I think that you will serve the industry by keeping the subject alive by continuing to print articles like Doctor Skilling's, and inviting discussion.

Yours very truly,
L. V. BEWLEY (A'27)
(General Transformer Engg. Dept., General Electric Co., Pittsfield, Mass.)

A Note on Symmetrical Components

To the Editor:

I am submitting herewith a short discussion on symmetrical components which is intended to be an addition to Dr. A. E. Kennelly's article "Computation of the Unbalance Factor of a Three-Phase Triangle When Lengths of Three Sides are Given" which appeared in the JOURNAL of the A.I.E.E., March 1927, p. 240.

In his article Doctor Kennelly develops formulas for computing the magnitude of the direct and reverse sequence components, when given the lengths of the three sides of the voltage triangle. In this discussion I develop a simple formula for the angle between the direct and reverse sequence components, the expression being in terms of the lengths of the sides of the voltage triangle.

In his article Doctor Kennelly gave (the mathematical equivalent of) the following expressions for computing the forward (positive phase or direct sequence) and backward (negative phase or reverse sequence) components of a dissymetric three-phase vector triangle:

$$d^2 = \frac{\dfrac{a^2 + b^2 + c^2}{3} + S^2}{2}$$

and

$$r^2 = \frac{\dfrac{a^2 + b^2 + c^2}{3} - S^2}{2}$$

where a, b, and c are the lengths of the vectors forming the triangle and S (A_s in Doctor Kennelly's article) is the side of an equilateral triangle having the same area as triangle $a\,b\,c$; d and r (e in Doctor Kennelly's article) are, respectively, the magnitudes of the direct and reverse sequence components.

It is the object of this note to obtain an additional expression for the angle between d and r in terms of a^2, b^2, and c^2, terms used in Doctor Kennelly's expressions.

Let the vector representation of a, b, and c be

$$a = d_a + r_a = d\,j\,0^0 + r\,j\,\theta_a \qquad (1)$$

$$b = d_b + r_b = d\,j\,240^0 + r\,j\,(120^0 + \theta_a) \qquad (2)$$

$$c = d_c + r_c = d\,j\,120^0 + r\,j\,(240^0 + \theta_a). \qquad (3)$$

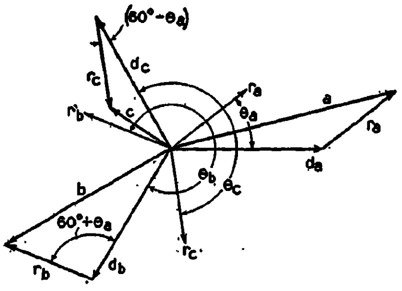
This is quite evident from the accompanying illustration.

By the law of cosines

$$b^2 = d^2 + r^2 - 2\,d\,r\cos(60^0 + \theta_a)$$

and

$$c^2 = d^2 + r^2 - 2\,d\,r\cos(60^0 - \theta_a)$$



Vector relations in an unbalanced three-phase system with direct and reverse sequence components

so that

$$\cos(60^0 + \theta_a) = \frac{d^2 + r^2 - b^2}{2\,d\,r}$$

$$= \frac{\cos\theta_a}{2} - \frac{\sqrt{3}\sin\theta_a}{2} \qquad (4)$$

$$\cos(60^0 - \theta_a) = \frac{d^2 + r^2 - c^2}{2\,d\,r}$$

$$= \frac{\cos\theta_a}{2} + \frac{\sqrt{3}\sin\theta_a}{2} \qquad (5)$$

Subtracting eq. 4 from eq. 5

$$\frac{b^2 - c^2}{2\sqrt{3}\,d\,r} = \sin\theta_a \qquad (6)$$

Adding eq. 4 and eq. 5

$$\frac{2\,d^2 + 2\,r^2 - b^2 - c^2}{2\,d\,r} = \cos\theta_a \qquad (7)$$

But by making use of Doctor Kennelly's expressions for d and r in terms of a, b, and c, eq. 7 can be changed to

$$\frac{2\,a^2 - b^2 - c^2}{6\,d\,r} = \cos\theta_a \qquad (8)$$

Eq. 6 must be divided by eq. 8 to obtain the final expression

$$\tan\theta_a = \frac{\sqrt{3}\,(b^2 - c^2)}{2\,a^2 - b^2 - c^2}$$

or

$$\theta_a = \arctan\frac{\sqrt{3}\,(b^2 - c^2)}{2\,a^2 - b^2 - c^2} \qquad (9)$$

If use is made of Doctor Kennelly's expressions for d and r, the extra labor required to obtain θ_a will be small since a^2, b^2, and c^2 occur in both expressions.

Assuming the same values which Doctor Kennelly used in his example, let

a = 1,100 volts
b = 1,000 volts
c = 900 volts whence
d = 996.61 volts and
r = 115.91 volts

Using the final eq. 9

$$\theta_a = \arctan\frac{+19\sqrt{3}}{+61} = +28^0\,20'$$

It is interesting to note that by a cyclical interchange of the terms in the expression for θ_a, expressions for θ_b and θ_c can be obtained as follows:

$$\theta_b = \arctan\frac{\sqrt{3}\,(c^2 - a^2)}{2\,b^2 - c^2 - a^2}$$

$$\theta_c = \arctan\frac{\sqrt{3}\,(a^2 - b^2)}{2\,c^2 - a^2 - b^2}$$

Substituting in these expressions for θ_b and θ_c the values for a = 1,100, b = 1,000, and c = 900 volts, θ_b and θ_c can be obtained.

Thus

$$\theta_b = \arctan\frac{-\sqrt{3}\,(40)}{-2} = +268^0\,20'$$

$$= +240^0 + \theta_a$$

and

$$\theta_c = \arctan\frac{+\sqrt{3}\,(21)}{-59} = +148^0\,20'$$

$$= +120^0 + \theta_a$$

Hence for a given voltage triangle of arbitrarily designated sides a, b, and c, θ_a will be the smallest angle, if a is made to represent the longest side of the given voltage triangle.

Very truly yours,
E. DE LA GARZA,
(Senior Student, 1931, Rice Institute,
Houston, Texas)

Editor's Note: In commenting upon this discussion Doctor Kennelly stated that, "Mr. de la Garza's note supplies an important element not covered by my 1927 article; namely, the computed phase relation between the two symmetrical-component machines, *i. e.*, the angle at which each should be clamped on the same rotor shaft in such a way that the two symmetrical systems, electrically connected in opposite directions, would produce identically the same dissymmetrical voltages as the actual dissymmetrical machine provides."

Has Man Benefited by Engineering Progress?

To the Editor:

I assume the invitation to comment on the articles so far published in the symposium "Has Man Benefited By Engineering Progress?" (ELECTRICAL ENGINEERING, Aug. 1931, *et. seq.*) applies also to the general subject and its implications, which constitute a challenge to all of us.

The belief that engineering progress does benefit man has been widely held, otherwise there would be few engineers. It is significant that the question of "benefit" becomes of particular interest during a depression, a phenomenon the recurrence of which recently was considered most improbable. However, depressions or their equivalent occurred long before engineering attained its present stature, so it is evident that engineering is only one of the many factors in the present situation.

The most important factor and the least studied is man himself. The general lack of knowledge regarding the basic human impulses and their significance is most unfortunate. One reason for this is the unpalatability of some of the available facts.

Difficulties in the way of dealing frankly with human impulses are analogous to those encountered by the early scientists in their endeavor to substitute natural law for the popular "supernatural whim" as an explanation of physical phenomena. Modern scientists and engineers do not encounter such serious opposition, but they too are obliged to revise frequently their pet theories to fit the facts, a somewhat painful process which should aid them in dealing with the human factor.

I contend we will never reach a satisfactory basis for human relations until the available knowledge of human beings is more widely diffused. If we are unable to deal adequately with the most important factor, we should not complain when the partial solutions otherwise obtained prove ineffective.

Sincerely yours,
C. T. WELLER (A'20-M'21)
(Electrical Engineer, General Engineering Laboratory, General Electric Company, Schenectady, New York)

Col. R. E. B. Crompton, now in his eighty-seventh year and distinguished for his pioneer work in the British electrical engineering industry, was internationally honored in London by a gathering of scientists presided over by his partner, Frank Parkinson, who described Colonel Crompton as the "grand old man of the British electrical industry." He was eulogized further by Prof. Luigi Lombardi of Italy, and by a toast of the entire electrical industry proposed by the principal American guest, Dr. A. E. Kennelly, of Harvard University, past-president of the Institute.

Personal

Dr. Michael I. Pupin Awarded John Fritz Medal

Michael Idvorsky Pupin (A'90, F'15, HM'28) past-president of the Institute and professor emeritus of electrical engineering at Columbia University, N. Y., has been selected as the recipient of the 1931 John Fritz Gold Medal. The award was made to him as a leading scientist, engineer, and author, and as inventor of the tuning of oscillating circuits and the loading of telephone circuits by inductance coils. The John Fritz Medal is the highest honor given by engineers of the United States and was awarded to Doctor Pupin unanimously by the joint board of sixteen prominent engineers representing the four Founder Societies and their aggregate membership of more than 60,000.

M. I. PUPIN

Doctor Pupin is professor of electromechanics and director of the Phoenix Research Laboratory at Columbia University, and of course is widely known for his contributions to long distance communication and for his advanced work in electrical resonance, the passage of electricity through gases, and many other scientific subjects. To many thousands of persons the fascinating story of his life has been made known through his inimitable autobiography "From Immigrant to Inventor" and his other writings. He was born a Serb in a Hungarian province Oct. 4, 1858. He came to America as a youngster and after courageous struggles won an opportunity for an education; was graduated from Columbia University in 1883. Thereafter he studied further and received a degree of doctor of philosophy from the University of Berlin; subsequently was granted his doctor of science degree by both Columbia and Princeton universities, and his doctor of laws degree by Johns Hopkins and New York universities, Muhlenberg College, and other educational institutions. He is a past-chairman of The Engineering Foundation and his affiliations include the American Association for the Advancement of Science, National Academy of Sciences, New York Academy of Science, American Philosophical Society, American Physical Society, and other learned organizations. During the World War he served on the National Advisory Committee for Aeronautics, and many other bodies doing scientific research for the government. Doctor Pupin's other honors include the Edison Medal of the A.I.E.E., and the Carson Gold Medal of the Franklin Institute. Among earlier recipients of the John Fritz Medal are Admiral David Watson Taylor (retired) of the U. S. Navy, President Herbert Hoover, Ralph Modjeski, John J. Carty, John F. Stevens, Ambrose Swasey, Guglielmo Marconi, Sir Robert Hadfield, Charles P. E. Schneider, and Elihu Thomson.

André E. Blondel (HM'12) professor at l'Ecole Nationale des Ponts et Chaussées, Paris, France, received certificate of Honorary Membership in the Illuminating Engineering Society at a special Silver Anniversary session held in Pittsburgh, Pa., October 14, 1931. The certificate was presented "in recognition of his contribution to science and the art of illumination as educator, scientist, engineer and inventor in the scientific design of light-distribution glassware, originator of great improvements in arc lights and of methods and apparatus for photometrical measurements; author of many memoirs on the theory and practise of illumination and of the units of measurement applicable thereto. A man whose courage has enabled him to overcome most formidable physical handicaps and whose knowledge and sympathy are of international scope." The certificate itself a masterpiece of artistic workmanship, together with its purport, made an especially suitable award for Mr. Blondel's achievements in the fields of professional art and science.

Dwight P. Robinson (F'13) has resigned from the presidency of United Engineers & Constructors, Inc., Philadelphia, Pa., having completed his work of coordination of the activities of the United Gas Improvement Contracting Company, Day & Zimmermann Engineering & Construction Company, the Public Service Production Company, and Dwight P. Robinson & Company, Inc. He is succeeded by E. M. Chance, vice-president. For over forty years identified with organizing and administrative work on outstanding construction enterprises, Mr. Robinson is a well-known figure in today's engineering field. His achievements with the Stone & Webster organization as well as the wealth of experience which he has acquired in the operation of its subsidiaries as early as 1913 placed him in the front ranks of the profession. His field of application has never been restricted one; in addition to his activities in electrical construction, he was, from 1913 to 1917 consulting chemist and engineer for anthracite and bituminous coal mining companies in Pennsylvania and West Virginia.

Elihu Thomson (F'13-HM'28) charter member and past-president of the Institute, on October 14 at a special session of the Illuminating Engineering Society's Silver Anniversary convention, Pittsburgh, Pa., had honorary membership in the I.E.S. bestowed upon him, "in recognition of his contribution to science and the art of illumination as an educator, scientist, engineer and inventor; distinguished as a pioneer in electric lighting and in the development of electric arts; in recent years renowned through his contributions to the technology of quartz and its application to illumination problems, particularly the preparation of specula of hitherto unattained dimensions; the recipient of many honors at home and abroad and beloved by all who know him."

President Skinner (F'12) recently was the guest speaker at the Silver Anniversary convention of the Illuminating Engineering Society, held in Pittsburgh, Pa., October 13-16, 1931. His address delivered at the special Silver Anniversary session which took place Wednesday evening briefly and interestingly sketched the "progress of illumination" from the time when he first saw an electric light, at a traveling circus, through the period of transformation twenty-five years had accomplished "to the point where it is equal in its efficiency to daylight." He also spoke of the use of illumination "as an artistic expression to such an extent that buildings, parks, and fountains become things of beauty after the night has fallen."

G. H. Harries (F'22) major-general U. S. A. (retired) formerly vice-president for H. M. Byllesby & Company, Chicago, Ill., and for nearly forty years representative of investors, operators, estimators and consumers of electric energy throughout the country, now has retired from the active engineering field. General Harries at various consecutive periods, has been treasurer of the National Electric Light Association, and president of the Association of Edison Illuminating Companies, the American Electric Railway Association and the Illumination Engineering Association. Upon retirement he has chosen Los Angeles, Calif. as a place of residence.

Lyman Winn (A'30) who has been doing sales engineering work with the Shelby Electric Company at Memhpis, Tenn., recently joined the engineering force of the Standard Electric Company there in like capacity. Mr. Winn was a member of the committee which wrote the constitution and by-laws of the Institute's Memphis section; he also has contributed to technical literature through the columns of *Mill & Factory*, an Illinois publication.

H. H. Anderson (M'27) who was engineer of special investigations for the Shell Oil Company, San Francisco, Calif., now is assistant to the president of the Shell Union Oil Corporation, New York, N. Y. Mr. Anderson was at one time a member of the executive committee of the division of development and production engineering of the American Petroleum Institute, and has published a number of technical articles in that field.

A. E. Kennelly, (F'13) professor emeritus of electrical engineering, Harvard University and Massachusetts Institute of Technology, Cambridge, Mass., has gone to Japan. At the invitation of the Institution of Electrical Engineers of Japan, he will deliver a group of lectures during November before five Japanese universities as the first visiting American professor under the Iwadare Foundation.

E. R. Davis (A'09) who has been manager of construction for the Southern California Edison Company, Ltd., Los Angeles, now has assumed additional duties as its manager of construction and engineering with executive supervision of both of these departments. Coincident with his new appointment his company has organized an engineering executive committee with Mr. Davis as a member.

T. H. MORGAN

T. H. Morgan (A'23) who has been assistant professor of electrical engineering, secretary of the electrical engineering faculty and assistant to the executive head of the department, at Stanford University, now has been called East to occupy the position vacated by Prof. H. B. Smith, head of the department of electrical engineering at Worcester Polytechnic Institute, Worcester, Mass. Professor Morgan, who is a native of Fredericton, New Brunswick, Can., received his early technical training at the University of British Columbia (1913-16), Stanford University (1917-1919-1920) followed by postgraduate studies in electrical engineering there (1928-1929). Before becoming assistant professor at Stanford University he was for four years an instructor. He has had also extensive practical experience in the superintendency of the Foundation Company, Victoria, B. C., as test engineer of the Inspiration Consolidated Copper Company, Arizona, and as engineer of the Great Western Power Company, San Francisco, Calif. In 1927 he was secretary of the electrical engineering faculty of Stanford University, counselor of the Stanford A.I.E.E. Branch, chairman of the committee on Student activities as well as of the committee on prizes and awards of the 8th District in 1929. Prof. Morgan is a member of the Society for the Promotion of Engineering Education, and a liberal contributor to technical literature.

C. W. Rice (F'12) secretary of the American Society of Mechanical Engineers, New York, N. Y., has been honored by Verein Deutscher Ingenieure at its 75th anniversary meeting in Cologne, when he was the recipient of its medal "in grateful appreciation of services to technical-scientific achievement, particularly in promoting mutual international interests."

A. V. Guillou (M'27) has resigned from the position as assistant chief engineer of the California Railroad Commission after four years of service in that position. He will now function as chief engineer for the newly formed Public Service Commission of Wisconsin. Mr. Guillou is well known in his work with the various power companies of California.

M. K. McGrath (M'27) vice-president of the International Telephone & Telegraph Corporation whose change of residence from London, England, to New York, N. Y. was posted in the July 1931 issue of Electrical Engineering, now is located with the Postal Telegraph-Cable Company in Chicago, Ill.

A. G. Ennis (A'31) who was engineering assistant in the mechanical department of the Philadelphia & Reading Coal & Iron Company, now is identified with the George Washington University, Washington, D. C., in the capacity of instructor in the electrical engineering department.

W. B. Massenburg (A'31) of Warrenton, N. C., recently has made new connections with the Westinghouse Electric & Manufacturing Company, at Philadelphia, Pa. He was at one time associated with the home office at East Pittsburgh, Pa., in the sales engineering department.

E. N. Willis (M'28) executive secretary of the University Club at Dallas, Texas, and at one time branch manager of the New Orleans branch of the Auto Men's Association, has opened his own business offices in the Electrified Ozone Water Company, Brownsville, Texas.

Winthrop Allen (A'30) who has been working with E. I. du Pont de Nemours Company, Wilmington, Del. as assistant electrical engineer now has associated himself with the Prudential Insurance Company, Newark, N. J., as electrical engineer of home office buildings.

C. L. Edgar (F'12) president and general manager of the Edison Electric Illuminating Company of Boston, recently was chosen chairman of the executive committee of the Society for Electrical Development. He already has served this society as president.

A. J. Grant (A'26) of the meter engineering department, Westinghouse Electric & Manufacturing Company, Newark, N. J., has removed to Ottawa, Ontario, Canada, where he will assume new duties in the physics department of the National Research Council.

C. E. Allen (F'14) previously southwest district manager for the Westinghouse Electric & Manufacturing Company, St. Louis, Mo., and subsequently at the East Pittsburgh works, now is located at Mansfield, Ohio, works of this company.

A. W. Manby (A'22) who was chief operator at the Queenston generating station of the Hydro-Electric Power Commission of Ontario, Niagara Falls, N. Y., has been transferred to its new Chats Falls plant, Fitzroy Harbour, Ontario.

William Shuler (M'24) who has been serving the Columbia Engineering & Management Corporation, Cincinnati, Ohio, as its electrical engineer now has made new connections with the Dayton Power & Light Company, Dayton, Ohio.

P. A. deMars (M'31) who was previously professor of electrical engineering at Tufts College as well as consulting engineer, Boston, Mass., recently was chosen technical director of the Shepard Broadcasting Service, Inc., in that city.

O. W. Walter (M'29) research engineer, Hall Electric Heating Company, Inc., Philadelphia, Pa., now is assistant professor in electrical engineering at The College of the City of New York and is residing at Hastings-on-Hudson.

W. Viessman (M'29) mechanical and electrical engineer, Bureau of Mechanical and Electrical Service, City of Baltimore, Md. now is engaged in an industrial consultant service of his own as mechanical-electrical engineer in that city.

R. L. Cotton (A'30) junior engineer with the New York Edison Company, New York, N. Y., has made new affiliations with the American Radio News Corporation, New York, N. Y., which he will serve as station engineer.

C. E. Crofoot (M'28) who previously was in the technical high school department of the Utica Free Academy, Utica, New York, now is in the technical school department of the Mount Pleasant High School, Schenectady, N. Y.

W. W. Macalpine (A'30) who has been radio engineer for the International Communication Laboratories, Mount Vernon, N. Y., has been chosen director of research, Communication Patents, Incorporated, at Ampere, N. J.

M. B. Wyman (A'30) who for some time was central station engineer of the general engineering department, Westinghouse Elec. & Mfg. Company, East Pittsburgh, Pa., now h s removed to this company's office at St. Louis, Mo.

A. J. Bronold (A'29) sales assistant of the Westinghouse Electric & Manufacturing Company's specialist group, Pittsburgh, Pa., has made recent affiliations with the Westinghouse Lamp Company, at Columbus, Ohio.

A. B. Chapman (A'29) who for some time has been serving the RCA Victor Company, Incorporated, as service engineer at Oklahoma City, Okla., now has taken up new work for that company at Dallas, Texas.

W. M. Young (A'24) of the department of electrical engineering, University of Iowa, Iowa City, Ia., has joined the engineering research department of the Taylor Instrument Company, Rochester, N. Y.

H. A. Barre (A'11) chief engineer of the Southern California Edison Company, Ltd., Los Angeles, serves with E. R. Davis on the recently created engineering executive committee of that organization.

H. B. Briggs, Jr. (A'30) who has been located in New York, N. Y. as electrical engineer for Theodore E. Ferris, has accepted position with the Bath Iron Works Corporation, at Bath, Me.

E. A. Preisel (A'30) who has been switchboard draftsman for the Westinghouse Elec. & Mfg. Company, Buffalo, N. Y., now has joined that company's forces at Newark, New Jersey.

H. Romander (A'28) engineer, Federal Telegraph Company, Palo Alto, Calif., has removed to Newark, N. J., where he will serve the Federal company in the capacity of radio engineer.

A. D. Pettee (A'20) consulting engineer for the General Cable Corporation at Perth Amboy, N. J., now is consulting engineer for accessories at the Chicago office of the corporation.

H. E. Gumbart (A'25) who was serving as division sales engineer for the Brown Company, Chicago, Ill., now has been transferred to the company's office at Portland, Maine.

G. K. Morrison (A'23) electrical engineer, Federal Telegraph Company, Palo Alto, Calif., has removed to Newark, N. J. where he is still serving this company.

S. L. Poohar (A'31) field service engineer for the RCA Photophone, Inc., Atlanta, Ga., has been transferred to that company's offices at Irwin, Pa.

J. S. Mahan (F'27) field engineer of Steel & Tubes, Inc., Chicago, Ill., now is serving Electrotrim, Incorporated, of that city, in like capacity.

Hugh Skilling (A'28) of San Diego, Calif., has removed to Stanford University, Calif., for university work there.

Obituary

Garnett Holstein Finks (A'16) engineer of the power sales division of the Alabama Power Company, Birmingham, Ala., with which he had been associated since 1922, died at his home September 18, 1931, of pneumonia. He was born at Bertha, Va., July 20, 1891, was a student in electrical engineering at the Virginia Polytechnic Institute, and immediately thereafter engaged in machine shop practise and general construction with the Mathieson Alkali Works. During the period 1912-1913 he was in the electrical departments of the Norfolk and Western Railway, where he was called upon to study a multiplicity of electrical application. In the subsequent position of chief electrician for the Gilliam Coal and Coke Company, the Arlington Coal and Coke Company, the Shawnee Coal and Coke Company and the Glen Alum Coal Company (in advisory capacity) he was given charge of all of their electrical and mechanical work involving maintenance and construction of power plants and machine shops. This was his position until he joined the U. S. government forces at the Hog Island Shipyard, thence to be transferred to the government aviation department at League Island. Shortly after the close of the war, Mr. Finks became connected with the Mill & Mine Engineers, at Birmingham, Ala., which led in 1922 to his being chosen power engineer of the sales department of the Alabama Power Company, his last position.

Harold Calvert (A'17) consulting engineer with the firm Calvert & Barnes, Philadelphia, Pa., died June 27, 1931, in Philadelphia, the city of his birth. He was born April 7, 1875. He attended the University of Pennsylvania, graduating in 1893 with the degree of B. S. in E. E.; in 1897 he obtained his E. E. degree from this same university. His first work in the practical field of electricity was on storage battery installations and switchboard design, in the drafting department of the Electric Storage Battery Company of Philadelphia. In 1900 he became draftsman for the firm of McIntosh & Seymour, Auburn, N. J., on engine design, and two years later he joined the Philadelphia Electric Company as draftsman on station design; later becoming inspector on station construction, and still later made estimating engineer for the writing of wiring specifications for light and power. From this work Mr. Calvert was promoted again to the charge of design and inspection of customers' installations, later forming his own company. In this practise Mr. Calvert but emphasized his already established reputation as a worthy consultant.

Gifford LeClear (A'97-M'28) prominent member of the engineering firm of Densmore, LeClear & Robbins, Boston, Mass., died at his home in Waban, Mass., September 24, 1931, at the age of 57. He was a native of Rutherford, N. J. He won his A. B. degree from Harvard University in 1895 and his A. M. in 1896. For three years he was assistant professor of physics at Harvard, later obtaining practical experience with the West End Street Railway. In 1898 his own company was formed, first as Densmore & LeClear and later as Densmore, LeClear & Robbins, architects and engineers. Mr. LeClear took charge of the electrical work. As an engineer he enjoyed a national reputation; his design and engineering skill is associated with the erection of the Harvard Medical School group of buildings in Boston, and for many years his genius was called upon for similar institutional work in this locality. He also served on a committee which laid out a comprehensive traffic signal system for the city of Boston. Many of this city's latest and most modern buildings are products of his ingenuity. He was one of the leading spirits of the city.

Joseph Bijur (A'94-F'13) president of the Bijur Lubricating Corporation, New York City, and Life Member of the Institute, died suddenly October 19, 1931.

Oliver Jackson Bushnell (M'19) superintendent of the meter department of the Commonwealth Edison Company, Chicago, Ill., died recently at his home in Hinsdale, Ill. He was born at Rockton, Ill., September 13, 1871. Shortly after being graduated from a classical course at Beloit College, he entered the employ of the Chicago Edison Company, and in 1895 was appointed superintendent of the meter department. As a member and later chairman of the meter committee of the Association of Edison Illuminating Companies he assisted in the preparation of the meter code; and as chairman of the N.E.L.A. meter committee, he instituted and supervised the preparation and publication of the Electrical Meterman's Handbook. In 1919 he joined the Commonwealth Edison Company to take direct charge of the customers' meter engineering including the 80,000 demand meters of the company. Only recently he was appointed to the committee of advisors on measuring instruments of the United States national committee of the International Electrotechnical Commission.

Cyril Thomas Wall (A'31) of St. Paul, Minn., died August 22, 1931. He was born at Evansville, Ind., March 30, 1906, and was student equipment engineer for the Northwestern Bell Telephone Co., chief engineer's department, Minneapolis, Minn. His degree of Bachelor of E. E. was conferred upon him by the University of Minnesota, June 1930.

Local Meetings

District 6 Executive Committee Meets at Omaha

On Sept. 28, 1931, the executive committee for the Institute's North Central District met in the Telephone Building at Omaha, Neb. Present were P. H. Patton (Omaha) District vice-president; N. R. Love and Dr. R. E. Nyswander of the Denver Section; H. F. Rice of Grand Forks, N. D.; A. L. Turner (Omaha) and Clarence Talsma (Omaha) of the Nebraska Section; and C. E. Skinner, president of the Institute.

Following Doctor Skinner's informal talk about Institute policies and problems, the committee turned to its routine business electing Vice-President Patton as District delegate on the national nominating committee, with A. L. Turner as an alternate. To serve on the District prize awards committee, H. S. Sands of Denver was appointed chairman of a committee to consist of himself, A. L. Jones of Denver, and C. D. Robison of Omaha.

Ways and means were discussed of stimulating greater participation in Institute affairs by both Members and Enrolled Students. It is contemplated that efforts will be made to stimulate the preparation and presentation of more papers by both Section members and students, so that there may be a larger number of papers available for prize competition. It was urged also that qualified persons contemplating trips through the District should be encouraged to arrange stop-overs in order to permit them to address the Student Branches particularly those farther removed from the headquarters of the District's two sections. In this connection also was mentioned the success attending the Denver Section's practise of holding its annual business meeting on the campus of the University of Colorado (Boulder) in cooperation with the students "engineers' day" activities.

District 2 Executive Committee Meets at Pittsburgh

To transact matters of routine business and to plan for future District meetings, the executive committee of the Institute's Middle Eastern District met at the Keystone Athletic Club, Pittsburgh, Pa., Sept. 15, 1931. Representatives present were: *vice-president*, W. B. Kouwenhoven (Baltimore, Md.); *secretary*, G. S. Diehl (Baltimore, Md.); *assistant national secretary*, H. H. Henline (New York); *Section chairmen*, R. R. Krammes (Akron, Ohio); K. A. Hawley (Baltimore, Md.); E. S. Fields (Cincinnati, Ohio); G. A. Kositzky (Cleveland, Ohio); P. R. Urich (Erie, Pa.); Morland King (Lehigh Valley); F. A. Connor (Pittsburgh, Pa.); R. M. Field (Sharon, Pa.); J. A. Dinwiddie (Toledo, Ohio); G. L. Weller (Washington, D. C.); *Section secretaries*,

R. A. Hudson (Akron, Ohio); John Wells (Baltimore, Md.); J. A. Noertker (Cincinnati, Ohio); F. E. Snell (Cleveland, Ohio); R. Mallory (Columbus, Ohio); C. V. Roberts (Erie, Pa.); J. L. MacBurney (Philadelphia, Pa.); T. Spooner (Pittsburgh, Pa.); *alternate for secretary,* F. R. Mueller (Washington, D. C.).

As District representative on the national nominating committee, F. J. Chesterman (A'20-F'22) of Pittsburgh, Pa., was elected and authorized to go uninstructed. As members of the District coordinating committee, in addition to the District vice-president and secretary, K. A. Hawley (Baltimore, Md.) G. L. Weller (Washington, D. C.) F. A. Connor (Pittsburgh, Pa.) and C. N. Johnson (Philadelphia, Pa.), Section officers, and Prof. J. T. Walther (Akron, Ohio) as student Branch counselor, were elected. To round out the District meeting committee, which is composed of the district coordinating committee and two members from the Section where the next proposed District meeting is to be held, K. A. Hawley, chairman of the Baltimore Section, appointed A. F. Bang and L. G. Smith.

To serve District No. 2 as a prize award committee, Dr. M. G. Lloyd, Washington, D. C., was elected to serve as chairman, along with Prof. T. D. Owens, (Cleveland, Ohio) and W. A. Hillebrand (Barberton, Ohio).

The District committee is planning for a 1932 fall District meeting to be held in Baltimore, and contemplates the possibility of a District meeting at Akron, Ohio, for the spring of 1933. Ways and means of stimulating Section activities were discussed and the desirability of pursuing unrelenting membership activities was emphasized.

N. Y. Section to Hear About Suburban Electrification

Suburban electrification will be the topic for discussion at a meeting to be held at 7:30 p. m. on Tuesday, November 10, 1931, in Room 1 of the Engineering Societies Building, 33 West 39 Street, New York, N. Y., by the Transportation Group of the Institute's New York Section.

G. A. Wright of the Reading Company will give a talk on the Reading electrification, describing the construction and illustrating with moving pictures the interesting steps leading up to inauguration of service.

R. M. White of the Delaware, Lackawanna & Western Railroad will outline the experiences of a railroad which has for the past year operated suburban traffic under electric power.

Future Section Meetings

Akron

November 10, 1931—Oil Purification, by R. P. Dunmire, Buckeye Laboratories, Inc.

December 8, 1931—Television, by J. O. Perrine, American Tel. & Tel. Co.

Cleveland

November 19, 1931—Engineering in Russia, by Arthur G. McKee, President, Arthur G. McKee & Co.

December 17, 1931—Behind the Scenes, by Dr. Zay Jeffries, metallurgical engineer and consultant; W. L. Enfield, manager, incandescent lamp development laboratory. Both of these speakers are with the General Electric Company at Nela Park. Joint meeting with the Illuminating Engineering Society.

Dallas

November 23, 1931—Communications, by H. S. Osborne, American Tel. & Tel. Co.

Detroit-Ann Arbor

November 10, 1931—Power System Stability, by Robert Treat, General Electric Company. Meeting to be held at Jackson, Mich.

December 1, 1931—Subject to be announced later. Meeting to be held at Detroit Edison Auditorium.

Lehigh Valley

November 13, 1931—Power System Operation, by George M. Keenan, superintendent of the Pennsylvania-New Jersey 220-kv. Interconnection. Arrangements have also been made to visit and inspect the Service Depot of the Metropolitan Edison Co. in Reading.

Pittsburgh

November 10, 1931—Lightning Protection of Overhead Transmission Systems, by W. W. Lewis, General Electric Co.

December 8, 1931—Recent Developments in Electrical Research, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co.

Rochester

November 9, 1931—Experimental Visual Broadcasting, by A. B. Chamberlain, Columbia Broadcasting System;

Advances in Ultra Short Wave Transmission and Reception, by Edward Karplus, General Radio Co. Joint meeting with the I. R. E.

Toledo

November 20, 1931—Power Transformer Design and Tap Changing Under Load, by L. H. Hill, Allis Chalmers Mfg. Co.

Talk by James Dinwiddie, Westinghouse Electric & Mfg. Co.

December 9, 1931—Television, Its Fundamental, Physical and Psychological Principles, by J. O. Perrine, American Tel. & Tel. Co.;

Protective Relays, by J. H. Hunt, Toledo Edison Co.

Past Section Meetings

Boston

Inspection trip through the new Herald-Traveler Building. October 3. Attendance 300.

Chicago

Industrial Russia, by John M. Carmody, editor, Factory & Industrial Management. Dinner preceded the meeting. Joint meeting with the Western Society of Engineers and the A.S.M.E. September 21. Attendance 650.

Cincinnati

Lighting for Health—Latest Types of Equipment and Methods of Application, by Carl E. Egeler, General Electric Co. Dinner preceded the meeting. September 10. Attendance 62.

Dallas

The Use of Electricity and Radiant Energy in Medicine, by Dr. Charles L. Martin. Illustrated with slides, charts, and demonstrations. September 26. Attendance 81.

Denver

Demonstration of Induction Between Power and Telephone Circuits, by H. R. Huntley, American Tel. & Tel. Co. September 9. Attendance 205.

Some Institute Problems, by C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Electric & Mfg. Co. Doctor Skinner showed motion pictures which he had taken during his recent world tour. Dinner preceded the meeting. September 25. Attendance 15.

Detroit-Ann Arbor

Aviation, by William B. Stout, Stout Engineering Laboratories. Mr. Stout described some of the difficulties which have been met in developing commercial aviation. Annual dinner meeting. September 15. Attendance 150.

Erie

Unemployment from Technological Standpoint, by Laurence A. Hawkins, General Electric Company. September 15. Attendance 75.

Houston

Production and Application of Light, by V. O. Clements, Westinghouse Electric & Mfg. Co.;

Electrical Equipment for Oil Field Operation, by I. T. Hockaday, General Electric Co.;

The Responsibility of Members of the A.I.E.E. to Their Local Section, by J. E. Sheehan, Houston Lighting & Power Co.;

Résumé of Lightning Protection on Transmission Lines, by E. J. Shimek, Rice Institute. The above papers were taken from articles published in Electrical Engineering and each was presented in approximately twenty minutes. Dinner preceded the meeting. September 17. Attendance 30.

Los Angeles

Some Institute Problems, by C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co.;

An Electrical Engineer's Part in Aviation, by C. F. Green, General Electric Co. Past-chairman H. W. Hitchcock and chairman P. S. Biegler gave brief reports of the Asheville and Lake Tahoe conventions, respectively. Dinner preceded the meeting. September 8. Attendance 96.

Louisville

Recreational meeting. September 25. Attendance 69.

Memphis

Tata Hydroelectric Development in West India, by M. Eldredge, Memphis Power & Light Co. September 8. Attendance 48.

Mexico

Dinner meeting at which the officers for the term 1931-32 were announced as follows: E. F. Lopez, chairman; L. Castro, secretary; F. Aubert, treasurer. September 22. Attendance 40.

Minnesota

A. A. Kearney, Manilla Electric Lighting & Power Co., gave a talk on interesting phases of his experiences in the Orient. September 22. Attendance 44.

Niagara Frontier

Some Engineering Features of the Niagara-Hudson System, by Norman R. Gibson, Niagara-Hudson Power Co.;

The New 60-Cycle Distribution System in Buffalo, by R. T. Henry, Buffalo, Niagara & Eastern Power Corp. Dinner was held at the Hotel Statler preceding the meeting. September 18. Attendance 120.

Oklahoma City

Taping of High Voltage Cable Joints, by R. Schaeffer, Byllesby Engineering & Mgt. Corp.;

Piloted Ground Wire Study, by J. D. Browder, Oklahoma Gas & Electric Co.;

The Asheville Convention, by C. T. Almquist, University of Oklahoma, and delegate of the Section to the summer convention;

The Kansas City District Meeting, by F. J. Meyer, Oklahoma Gas & Elec. Co. Dinner preceded the meeting. September 21. Attendance 70.

Pittsburgh

Inspection trip through the plants of the Pennsylvania Rubber Co. and the Paramount Rubber Co. Joint meeting with the Engineers' Society of Western Pennsylvania. September 15. Attendance 195.

Portland

Recollections, by O. B. Coldwell, General Electric Co. Dinner meeting. September 22. Attendance 55.

St. Louis

Social meeting. September 23. Attendance 205.

San Antonio

F. A. Dale, Emory Peck & Rockwood, spoke about the Hamilton Dam under construction on the upper Colorado river. Illustrated with slides. September 22. Attendance 42.

San Francisco

Some Institute Problems, by C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Electric & Mfg. Co. Doctor Skinner showed several films taken on his recent trip around the world. Meeting was preceded by a dinner. September 11. Attendance 82.

Some Thoughts on Waves, by O. B. Blackwell, American Tel. & Tel. Co. Illustrated with slides. Dinner meeting. October 2. Attendance 156.

Sharon

Lightning Surges on Transmission Lines, by J. J. Torok, Westinghouse Electric & Mfg. Co. October 6. Attendance 112.

Spokane

Report of Summer Convention and Brief Description of Papers Presented at Asheville, by L. A. Traub, Home Tel. & Tel. Co., and delegate of the Section. September 25. Attendance 7.

Toledo

Results of Seven Years Radio Interference Investigation, by Fred C. Helwig, Toledo Edison Co.;

Symmetrical Components, Theory, and Application, by B. C. Harker, Westinghouse Elec. & Mfg. Co. September 25. Attendance 55.

Toronto

Economics, A Challenge to the Engineer, by Roy V. Wright, president A.S.M.E. Short talks by S. G. Porter, president, Engineering Institute of Canada, and L. B. Chubbuck, Canadian Westinghouse Co., Ltd., vice-president, Canada District No. 10, A.I.E.E. Joint meeting with the A.S.M.E. and Engineering Institute of Canada. October 2. Attendance 125.

Utah

Some Institute Problems, by C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Electric & Mfg. Co. Doctor Skinner showed and explained some pictures of the Orient taken on the occasion of his visit to that part of the world when he was a delegate to the World Engineering Congress. September 15. Attendance 75.

Vancouver

Inspection trip to the new fire alarm headquarters. C. C. Mulligan gave a description of the central fire alarm system and conducted the party through the various rooms of the building. September 12. Attendance 30.

Past Branch Meetings

University of Arkansas

Study of Electrical Grounds, by Ned Muse, student. October 6. Attendance 33.

University of California

Prof. G. E. Beggs, Princeton University, gave a talk on the design of suspension bridges and other structures.

Illustrated. Joint meeting with the A.S.C.E. and A.S.M.E., to which the public was invited. September 3. Attendance 450.

Initiation banquet. MOKELUMNE RIVER AND SALT SPRINGS PROJECT, by O. W. Peterson, Pacific Gas & Electric Co.;

JOSEPH HENRY, by Kenneth Hines, student. September 11. Attendance 41.

V. T. Johnson, chairman, gave a synopsis of his trip to the Pacific Coast convention held at Lake Tahoe in August. Prof. B. L. Robertson outlined his experiences with the General Electric Co. and at Pennsylvania State College. Prof. T. C. McFarland gave a talk on his trip to the east and his experiences at the Bell Telephone Laboratories, Inc., in New York. September 23. Attendance 57.

Clemson Agricultural College

LIGHTING DISTURBANCES, by A. S. Teague, student;

A TALK ON TELEPHONES, by W. M. Thames, student;

INDUSTRIES NEW RESPONSIBILITIES, by L. C. Black, student;

CURRENT EVENTS, by J. M. Turner, student. Short talks by Prof. S. R. Rhodes, counselor, and G. C. Jones, student. October 1. Attendance 46.

University of Denver

ADVANTAGES OF STUDENT MEMBERSHIP, by Prof. R. E. Nyswander, counselor;

FIELDS OF THE A.I.E.E., by L. C. Trussler, Branch chairman. September 21. Attendance 18.

Film "Big Deeds." September 29. Attendance 31.

University of Kansas

Mr. Evanson, General Electric Co., gave a demonstrated lecture on carrier currents superimposed on power lines. Illustrated. October 1. Attendance 85.

University of Kentucky

Election of officers as follows: W. A. Hunter, chairman; H. F. Day, secretary-treasurer. September 16.

HISTORY, AIMS, AND PURPOSES OF A.I.E.E., by Prof. W. E. Freeman, counselor, and vice-president, Southern District No. 4, A.I.E.E. September 30.

University of Louisville

ELECTRIC WELDING, by W. Stafford, student;

OIL FILLED CABLES, by C. Best, student. July 17. Attendance 11.

Missouri School of Mines & Metallurgy

Election of officers as follows: W. O. Woods, chairman; Wm. Pickles, vice-chairman; H. W. Short, secretary-treasurer. Three films shown as follows: "Pictures by Wire," "Voices Across the Sea," and "That Big Little Fellow." September 30. Attendance 18.

University of Missouri

Prof. M. P. Weinbach, counselor, spoke in detail concerning the purpose and organization of the A.I.E.E. Election of officers as follows: James E. Shepherd, chairman; Alfred L. Coffman, vice-chairman; Leslie E. Bates, Jr., secretary-treasurer. September 30. Attendance 50.

University of Nebraska

General discussion of programs for future meetings. September 30. Attendance 9.

Newark College of Engineering

MAGNETIC TESTING, by Mr. Shedd, student. Election of officers as follows: Edward Olsta, president; John G. Woehling, vice-president, Albert E. Day, secretary; George Barker, treasurer. September 21. Attendance 29.

University of North Carolina

Talks on the advantages of student enrolment in the A.I.E.E. by Profs. J. E. Lear, Bennett, and E. W. Winkler. October 1. Attendance 40.

Pennsylvania State College

Annual smoker. October 7. Attendance 90.

Pratt Institute

W. H. Sutton, chairman, gave a brief account of last year's activities and explained the purposes of the Student Branch and the advantages of membership in the A.I.E.E. September 24. Attendance 32.

Inspection trip to the Hudson Avenue plant of the Brooklyn Edison Co. October 5. Attendance 43.

Rice Institute

AIMS AND ACTIVITIES OF THE A.I.E.E., by Prof. J. S. Waters, counselor. September 30. Attendance 22.

University of South Carolina

Prof. T. F. Ball, counselor, gave a résumé of the activities at the Summer Convention held in Asheville, last June. October 2. Attendance 35.

Southern Methodist University

The advantages of student enrolment in the A.I.E.E. were presented by Prof. H. F. Huffman, counselor. Election of officers as follows: J. V. Melton, chairman; R. W. Smith, vice-chairman; R. L. Allen, secretary-treasurer. September 9. Attendance 34.

General discussion of plans for future meetings. October 7. Attendance 15.

University of Vermont

LIFE AND WORK OF FARADAY, by Donald E. Child, chairman. September 28. Attendance 20.

Virginia Military Institute

THE LIFE OF FARADAY, by S. N. Garret, student;

PHOTOGRAPHIC AERIAL SURVEYING, by W. R. Fuller, student;

ELECTRIC WELDING, by L. DeCamps, student;

LIFE OF GEORGE WESTINGHOUSE, by S. R. Chisman, student. Prof. S. W. Anderson, counselor, explained the organization and purpose of the A.I.E.E. and welcomed the new students. September 26. Attendance 76.

Virginia Polytechnic Institute

Discussion of Branch activities for the coming year. September 24. Attendance 21.

EXPANSIONS AND IMPROVEMENTS BEING MADE IN ELECTRICAL POWER PLANTS, by R. C. Hoffman, student;

COMMUNICATION, by M. W. Bowery, student. P. H. Cross elected secretary. October 1. Attendance 45.

West Virginia University

Election of officers as follows: A. W. Friend, president; D. C. Kennedy, vice-president; Philip Skaff, secretary, H. V. Locker, treasurer. September 21. Attendance 30.

The following talks were given by students:

FORD CHANGES FROM D-C. TO A-C., by L. Palmer;

RAILWAY ELECTRIFICATION, by D. C. Kennedy;

ELECTRIC LIGHTING BEFORE EDISON, by R. H. Colborn;

PRESSURE INDICATOR ON A DIESEL ENGINE, by J. Kayauha;

PENTODE VACUUM TUBES, by A. W. Friend. Prof. A. H. Forman, counselor, gave a short talk on the benefits of student enrolment in the Institute. September 28. Attendance 30.

The following talks were given by students:

PROGRESS IN ENGINEERING, by L. P. Kerwin;

POWER EXPLOITATION IN SWITZERLAND, by W. McMillian;

COPPER, by R. W. Blair;

POWER TRANSMISSION IN SOUTH AFRICA, by L. Post;

INJURIES PRODUCED BY SURGE DISCHARGES, by J. L. Simpson;

X-RAYS, by J. E. Wallace;

VACUUM TUBES, by F. Q. Brown;

SHORT RADIO WAVES, by N. I. Hall. October 5. Attendance 30.

Employment Notes

Of the Engineering Societies Employment Service

Position Available

SALES ENGINEER. An electric cable manufacturer wants a man to manage one of its branch sales offices. He must have a thorough electrical engineering education, either university or practical training. He must have had sales experience in the industrial field. He must have had sufficient executive experience to handle and direct men. If you do not have all three requisites please do not apply. If you have here is a real opportunity. W-2758 C.

Men Available

ELECTRICAL ENGINEERING GRADUATE, age 22, B. S. in E. E. from well-known engineering college. Ten months' experience on construction. Desires employment with utility, engineering, or manufacturing concern. References furnished. Available upon short notice. C-9885.

ELECTRICAL ENGINEER, 33, married, B. S. in E. E. Ten years' experience as engineer with utility company. Familiar with design of lines and stations; accounting set-ups; executive duties and powers; modern business practise; now studying corporation law. Available at once. C-4734.

1931 GRADUATE of five-year cooperative school in electrical engineering. E. E. degree, age 28, single. Cooperative experience includes machine shop practise, telephone central office trouble shooting, and experience with large municipal fire alarm system. Desires position with manufacturing concern or public utility. Willing to start at bottom. Location, Middle West preferred, but elsewhere satisfactory. C-9825.

ELECTRICAL ENGINEER, graduate Lehigh University '22. Experienced in all kinds of construction, transmission work, power plants, substations, etc., chiefly as draftsman laying out such work. Familiar with electrification in anthracite fields. Willing to accept drafting, engineering or any other electrical position. Eastern States preferred but anywhere considered. C-9723.

ELECTRICAL ENGINEER, technical school graduate. Thoroughly familiar with the layout and design of power and substations having held position of engineering supervisor with large public utility for the past ten years. Experienced in organization and maintenance of meter test department. Speaks Portuguese; seven years' foreign experience. Available at once. C-9886.

1931 ELECTRICAL ENGINEERING GRADUATE of midwestern university. Age 22, single. Experience limited but includes technical work acquired from summer employment with street railway and ceramic industry. Courses taken include vacuum tube control devices and radio. Desires position with manufacturing or engineering concern. C-9879.

ASSOCIATE ELECTRICAL ENGINEER, 37, married. Twelve years with Westinghouse; apprentice course, sales and shop. One and one-half years western electrical engineering department, writing inspection methods instructions. Knowledge of oscillograph testing and meters. C-8817.

ELECTRICAL ENGINEER, 21, single, B. S. degree in E. E., A & M College of Texas, 1931, holder of government broadcast class operator's license. Two years' experience in radio work. Desires position in radio or telephon industries. Available at once. Will go anywhere. C-9588.

GRADUATE ELECTRICAL ENGINEER, 22, single, B. S. degree in E. E., University of North Carolina, 1931. Four years' experience in radio work. Desires position in radio or vacuum-tube industries; excellent references; location immaterial; available upon two weeks' notice. C-9896.

1924 GRADUATE ELECTRICAL ENGINEER available at once. Six years' research and practical experience on insulation and cables of all kinds. Two years' work on inductive coordination. Best of references. C-2282.

1931 GRADUATE ELECTRICAL ENGINEER, B. S. degree, single, age 22, American. Desires position in the electrical industry with an opportunity for advancement. Location, immaterial. Available immediately. C-9909.

1930 ELECTRICAL ENGINEER, Drexel Institute, 24, single, in very good health, 1½ years' experience in making complete electrical tests on distribution, power and rectifier transformers, and metering equipment. Also G. E. Test floor experience. Desires position with public utility, or industrial concern. Available at once. Location, immaterial. C-9913.

CONSULTING ENGINEER, New York City, having good connections with companies building high voltage switching stations, seeks to represent in the East first class concern manufacturing equipment for same. C-9332.

TECHNICAL GRADUATE in electrical engineering, 29, single, 1½ years G. E. Test; over ten years' experience with leading electrical company in repair, testing of electrical apparatus. Desires position in testing and experimental work on motors, generators, etc. Future prospects considered more important than initial salary. Best of references. Available short notice. C-8778.

RECENT GRADUATE wants to use scientific and engineering knowledge as background for commercial and management activities. Desires connection with leading concern, salary secondary. Foreign languages, long residence abroad, good references. C-9920.

GRADUATE ELECTRICAL ENGINEER, 1925, 28, single, year and a half G. E. Test, two years electrical construction in plants and substations for large utilities, one year superintendent electrical construction in steam plant and substations in Brazil. Desires position with utility on construction or operation work. Location, immaterial. C-4770.

PLANT MANAGER OR CONSTRUCTION SUPERINTENDENT. Graduate electrical engineer, 39 years of age, with some experience in heavy chemicals. Fifteen years of varied experience in utility operation, factory management, production engineering, radio and construction. Available at once. Location, immaterial. B-7340.

ELECTRICAL ENGINEER, B. S. E. E. degree from southern university, 1931, age 21, single. Desires position with manufacturing concern offering a future, or as instructor in electrical engineering. Location, immaterial. Available at once. C-9607.

ELECTRICAL ENGINEER, 28, single. Graduate Georgia Tech '29, B. S. in electrical and civil engineering. Westinghouse Test floor, engineering school and design school. One year's experience in turbine generator design including development work. Desires position with future. Location, immaterial. Available immediately. C-9923.

ELECTRICAL ENGINEER, B. S. in E. E., Case '29, age 25, single. Two years' varied experience with General Electric Company. Desirous of position with opportunities. Available immediately. C-9918.

1931 ELECTRICAL ENGINEERING GRADUATE, age 22, single, B. S. in E. E. at Carnegie Tech. Tau Beta Pi. Experienced in drafting and power substation construction. Desires position in railroad electrification or operation, or with other power engineering firm. Location, immaterial, Available immediately. C-9925.

GRADUATE ELECTRICAL ENGINEER, 1929, Ohio State University. Age 26, married. Tau Beta Pi. One year Westinghouse student course. Sixteen months motor engineering, mostly synchronous motor design. Motor and control test experience. Good references. Available immediately. C-9924.

ELECTRICAL ENGINEER, Pratt graduate 1931. Some experience with resistor units, also with vacuum and photocell tubes. Has had office work in graphs, data, reports. Interested in airport lighting, television, and sound. Eastern location preferred. C-5636.

PATENT ATTORNEY, graduate engineer, connected with a well-known firm specializing in foreign applications. Desires to make a new connection. Familiar with design and development of small electrical and mechanical parts. C-846.

ELECTRICAL ENGINEER, 22, single, University graduate '31. Desires junior position in test or design departments of power machinery manufacturing concern. Experience limited. Location preferred, Eastern. Available upon short notice. C-9447.

ELECTRICAL ENGINEER, 40, married, graduate Federal Technical University, Zurich, Switzerland. Experienced in design, construction, operation of power stations, substations, transmission lines, purchasing electrical equipment, duct lines and cable work, railroad electrification, catenary design, extensive knowledge, pleasing personality. Available now, location, immaterial. C-683.

EXECUTIVE OR STAFF ASSISTANT, engineering education. Fourteen years' broad experience with manufacturing, utility, and industrial surveys covering: cost reduction, production planning, standards, wage incentives, scientific management methods, statistical control systems, expense, and cost analysis. Capable organizer. Profitable assistant to busy executive. Prefers East. Consider any proposition. B-9122.

ELECTRICAL ENGINEER, graduate recognized southern university, 34, married, G. E. Test; broad experience utility field, particularly underground systems, including

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
L. E. Griffith, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

design, maintenance of low voltage a-c. networks. Desires position with utility with responsibility for design or maintenance of underground, overhead system, or manufacturer working on design problems. Location preferred, Middle West or Southwest. C-1191.

PHYSICIST, middle-aged, experience in industrial research, supervision of research, executive work and teaching physics for engineering and other classes of students. Advanced degrees in physics from prominent American universities. Emphasis of electrical subjects in training and teaching. Stability and opportunity desired. Available upon short notice. C-7900.

ELECTRICAL ENGINEER, 33, married, graduate of Worcester Polytechnic Institute, 1921, B. S. in E. E. Two years' experience in railway work, eight years in engineering, design, purchase of equipment, and construction of power stations, switching stations and substations. Desires sales engineering work. Location, New York Metropolitan preferred. Available immediately. C-9928.

GRADUATE ELECTRICAL ENGINEER, B. S. in E. E. 1928, M. S. in E. E. 1929. Completed Westinghouse Graduate Student and Electrical Design school courses. One year's experience induction motor designer; six months laboratory instructor. Desires position as instructor on university staff or engineer with manufacturing concern. Location, United States. C-9936.

ELECTRICAL ENGINEER, M. S. 1931 from M. I. T. G. E. Test including railway American, age 22, married. Desires connection with electrical company or public utility or as instructor in electrical engineering, physics, or mathematics. Location, immaterial. C-9942.

GRADUATE ELECTRICAL ENGINEER, 28, single, B. S. in E. E. from University of Minnesota, eighteen months General Electric Test, twenty-three months telephone and telegraph engineering. Desires position with manufacturing or public utility company. Location and remuneration considered secondary to opportunity offered for future. Available at once. C-9285.

ELECTRICAL ENGINEER, 22, B. S. E. E., 1930. Desires connection with public utility, electrical or radio manufacturing company. G. E. Test experience. Six months work with vacuum tubes. Experience with large motors. Location, immaterial. C-9806.

EXECUTIVE, Industrial physicist, technical graduate with diversified research experience and excellent engineering training, desires position with American organization. Will also consider opening as assistant to able engineer or business executive. B-8987.

COMMUNICATIONS ENGINEER Twenty years' telephone, telegraph, and radio inside and outside construction and maintenance experience, mostly abroad. Considerable knowledg modern high speed telegraph systems, relays and circuits. Wire experience on wiring diagrams. Switchboards, etc. Could economically modernize communication systems preferably abroad. C-8805.

ELECTRICAL ENGINEER, 23, degree B. S. in E. E. University of New Hampshire '30. Fourteen months G. E. Test and general course. Test xperience in transportation, motors, and generators and vacuum tubes. Nine months' summer work in main line electric railway shops. Interested in any engineering work. Available n short notice. C-9859.

GRADUATE ELECTRICAL ENGINEER, ag 28, married. Four years' experience in power plant and substation design. Eighteen months in signal department of a rapid transit railroad. Western Electric training course for switchboard engineer. Can refer freely to past connections. Location immaterial. Available now. C-9944.

GRADUATE ELECTRICAL ENGINEER, 42, married. Sixteen years' experience in design of small and fractional horsepower motors including polyphase different types of single-phase now on market and d-c. motors. Considerable experience in manufacturing, testing and cost analyzing. C-9951.

COST REDUCTION ENGINEER, cooperative engineering graduate, 1927, B. S. in E. E., desires position with manufacturer of electrical or mechanical products. One requiring experience in plant layout, improvements, material handling, machine shop practises, chart and statistical analysis. Would also consider technical report work with an industrial appraiser. C-9916.

ELECTRICAL ENGINEER, 45, university graduate, experienced in th various branches of electrical engineering work of power companies, including work for industrial customers, desires position with power company or manufacturer. Permanent position desired, but will consider temporary work. B-1928.

ELECTRICAL ENGINEER, age 39, married, technical graduate, B. S. E. E. 1913. Eighteen years' experience in the public utility field. For the past eight years chief draftsman in charg of large department doing substation and power house design. Seeks new connection as company is dissolving. Available immediately. C-9953.

ELECTRICAL ENGINEER, 33, with eight years' experience in erecting and installing electrical machinery and control apparatus. Also previous factory testing. C-9954.

ELECTRICAL ENGINEER, 21, single, 1931 graduate with B. S. in E. E. Member of honorary fraternity in college and won scholarship three consecutive years. Summer experience with public utility. Interested in any electrical engineering field including vacuum-tube work. Available at once. Location, New York preferred, but not essential. C-9467.

RADIO ENGINEER, age 31, married, B. S. in E. E. from one of the greatest Western universities. Has broad theoretical and practical experience in radio engineering. Available at once. New York City preferred. C-6734.

PUBLIC UTILITY ENGINEER, technical college graduate, age 37. Twelve years' diversified experience in all branches of the utility business. Valuation work, rate investigation, cost analysis, statistical and financial research, engineering and sales work. Services offered to any company requiring a trained public utility man. B-9782.

1931 ELECTRICAL ENGINEERING GRADUATE, age 22, B. S. E. E. in well-known engineering college. Desires connection with manufacturing or public utility concern. Four months' experience with a large power company. Michigan or bordering states preferred. Available immediately. C-9940.

ELECTRICAL ENGINEER, 35, single, M. I. T., general business experience, hydro-electric station operator one year; taught E. E. in university 1½ years; preparation of instruction books for electrical and mechanical apparatus 3½ years. Desires position in research and development or as instructor. New York City preferred but not essential. Available immediately. C-2481.

GRADUATE ELECTRICAL ENGINEER, 25, single, B. S. in E. E., 1930 Mid West college. One year G. E. Test including work on railway motors, control equipment and locomotives. Railway or public utility work preferred. Location anywhere. Salary secondary to opportunity. References. Available immediately. C-9958.

GRADUATE ELECTRICAL ENGINEER, 23, of Rensselaer Polytechnic Institute, desires position in public relations department of power and light utility company. Two years of varied power and light experience. Location, immaterial. C-9957.

DESIGN ENGINEER, college graduate, 38, married. Nine years electrical substation and power house design, with switchboards, wiring diagrams, and all other important items. Five years testing engineer power station and research laboratories. Speaks Spanish, German, and Hungarian fluently. Available for immediate offer. Location, U.S.A. or any foreign country. C-9128.

ELECTRICAL ENGINEER, 1930 graduate; cooperative experience on machinery layout and power wiring; recently employed elevator appliance design, layouts, test, reorganization. Eastern Pennsylvania preferred. C-9963.

ELECTRICAL ENGINEER, 35, married with 15 years' experience. One year G. E. Test. Two years U. S. Navy. Twelve years with manufacturer of control specialties. Vast experience with elevators and elevator accessory equipment. Desires engagement with elevator manufacturer or one manufacturing a varied line of control apparatus. Locate anywhere. C-9956.

ELECTRICAL ENGINEER, 30, desires new location. Responsible, keen, with a good record covering 8 years' experience in the design, construction and operation of generation, transmission and distribution. Also successful experience in rating, public relations. Special studies made of rural distribution and service. C-9959.

SALES ENGINEER, 22, single with automobile. B. S. in E. E. Georgia Tech., 1929. Experience in all departments of a Southern utilities corporation. Eight months' sales experience. Available anytime, anywhere. C-9965.

INDUSTRIAL ELECTRICAL ENGINEERING GRADUATE, Pratt Institute 1931, 21, single. Specialized in high frequency circuits. Three years' experience in the radio field. Desires work with radio or sound concern. Available immediately. Location, East. C-9904.

JUNIOR ENGINEER, 1931 graduate, B. S. E. E. University of Alabama. Desires position with utility, construction, manufacturing company. Location immaterial. Experienced in power plant and building installation and industrial control, having been employed for eight summer months and one full year first as electrician's helper and then as first class electrician. C-9446.

SALES EXECUTIVE: with electrical training. Seven years' experience in sales engineering and sales through distributors. Well acquainted with sales conditions in various parts of country. Willing to tackle difficult job. C-5431.

ELECTRICAL ENGINEER, 1931 graduate State University, B. S. degree E. E. and M. S. degree I. E. Single, 24. Experienced electrician on construction work with limited experience as estimator in same field. Desires connection with engineering, manufacturing, or large contracting concern. Any location acceptable; South America preferred. Available upon short notice. C-9970.

ELECTRICAL ENGINEER, graduate, married, 28, with wide experience in industrial plant electrical construction and maintenance; railway electrification; power plant design, estimating, and supervisory construction experience with electric contractor; cost analysis. Desires position with future. C-4428.

DISTRICT SALES MANAGER OR MANUFACTURER'S AGENT, experienced engineering representative, desires connection with high-grade company that has line of industrial or utility equipment. Eastern location preferred. B-4067.

ELECTRICAL, MECHANICAL ENGINEER, college graduate with wide practical experience in power plant work and industrial electrical equipment. Desires connection, available immediately. B-2492.

Membership

Recommended for Transfer

The Board of Examiners, at its meeting of September 28, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

To Grade of Member

BURNETT, JAMES HENRY, asst. engr., Brooklyn Edison Co., Brooklyn, N. Y.

CORY, SAMUEL I., telephone engr., American Tel. & Tel. Co., New York

CURRIE, FRANK L., engg. asst., Western Union Telegraph Co., New York.

FITZGERALD, EDWARD B., elec. engr., The J. G. Brill Co., Philadelphia, Pa.

FOUST, CLIFFORD McCLAIN, elec. engr., General Elec. Co., Schenectady, N. Y.

GIERING, PERCIVAL L., consulting, elec. engr., City of Boston, Transit Dept., Boston, Mass.

GILMAN, WILLIAM F., executive adviser to management, Kwang Tung Electric Supply Co., Canton, China; residence, Belgrade Lakes, Main .

HANNAFORD, EARLE S., supervisor of education and training, American Tel. & Tel. Co., Atlanta, Ga.

JACOBY, S. CLIFFORD, supt., transmission and distribution, Montaup Electric Co., Fall River, Mass.

LONGFIELD, CLAUDE M., electrolysis engr., State Electricity Commission of Victoria, Victoria, Australia.

McCLENAHEN, R. A., engg. asst., United Engineers & Constructors, Inc., Newark, N. J.

OSBORNE, R. W., president, Osborne Electric Co., Toronto and Niagara Falls, N. Y.

PARRACK, VASCO R., engr., Tennessee Public Service Co., Knoxville, Tenn.

SCHLENKER, VESPER A., consulting acoustical engr., New York.

SMITH, JR., S. ARCHIBALD, asst. engr., transmission, Public Service Electric & Gas Co., Newark, N. J.

WEIL, JOSEPH, instructor, consulting engr., University of Florida, Gainesville, Fla.

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before November 30, 1931.

Arthur, A. L., Syska & Hennessy, New York, N. Y.
Baxter, F. I., Kansas City Public Service Co., Kansas City, Mo.
Beck, Wm. O., Kelly Island Lime & Transport Co., Clay Center, Ohio
Bennett, W., Loew's Columbia, Warner Bros., Tivoli, Universal Pictures Corp., Rialto Theatres, Washington, D. C.
Brown, T. A. (Member) Madison Gas & Electric Co., Madison, Wis.
Brucker, R. K. (Member) J. G. Wray & Co., Chicago, Ill.
Cartmell, R. H., 2008 E. Live Oak, Temple City, Calif.
Collins, I. W., Pacific Gas & Electric Co., Oakland, Calif.
Crossley, H. R., Dominion of Canada, St. John, N. B., Can.
Dahlem, J. G., Richard Kaupert, Milwaukee, Wis.
Danko, J. T., University of Pittsburgh, McKeesport, Pa.
Den Braven, G., L. Bamberger & Co., Newark, N. J.
Dilts, C. B., Oklahoma Gas & Electric Co., Oklahoma City, Okla.
Dunklin, G. T. (Member) Westinghouse Elec. & Mfg. Co., New York, N. Y.
Edwards, L. C., Pacific Gas & Electric Co., Emeryville, Calif.
Fox, L. H., Mississippi A. & M. College, A. & M. College, Miss.
Goodhue, Wm. M., Harvard University, Cambridge, Mass.
Griffith, L. A., Emerson Elec. Mfg. Co., Richmond Heights, Mo.
Hartman, E. R. (Member) Telephone Bond & Share Co., Kansas City, Mo.
Henderson, R. M., National Light & Power Co., Moose Jaw, Sask., Can.
Hottle, W. M., Western Electric Co., Kearny, N. J.
Howe, P. B., Philadelphia Electric Co., Philadelphia, Pa.
King, F. H., Holyoke Gas & Electric Dept., Holyoke, Mass.
Kitchen, W. A., Oklahoma Gas & Electric Co., Oklahoma City, Oklahoma
Klitten, A. H., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Lloyd, T. C., Antioch College, Yellow Springs, Ohio
Loewe, R., University of Wisconsin, Madison, Wis.
Lundelius, O. E., City of Austin, Austin, Tex.
Miller, J. F., Louisville Gas & Elec. Co., Louisville, Ky.
Milligan, L. S., Long Island State Park Commission, Babylon, L. I., N. Y.
Omar, S., General Electric Co., Schenectady, N. Y.
Poppe, F. W., 1282 Shakespeare Ave., New York, N. Y.
Porter, H. F. (Member) Allegheny Steel Co., Brackenridge, Pa.
Randel, E. S., Southwestern Bell Telephone Co., Kansas City, Mo.
Rowley, R. A., 23 Girard Ave., Hartford, Conn.
Sargent, F. J., Madison Gas & Electric Co., Madison, Wisconsin
Sewell, F. N., Texas Power & Light Co., Dallas, Texas
Sklar, H. L., Micamold Radio Corp., Brooklyn, N. Y.
Urbany, J. E., Coyne Electrical School, Chicago, Ill.
Vidmar, P. J., Illinois Testing Laboratory, Chicago, Ill.
Walch, D. E. (Member) General Electric Co., Boston, Mass.
Watts, J. H., Westinghouse Elec. & Mfg. Co., San Antonio, Tex.
Whitmore, R. E., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
43 Domestic

Foreign

Castells, C. L., Ericsson Sudamericana, Buenos Aires, Argentina, So. America
Dunlop, R. P., Hong Kong Electric Co., Ltd., Hong Kong, China
MacAlpine, R. W., British Thomson-Houston Co., Ltd., Rugby, Eng.
Repetto, E. L., Rivadavia 3079, Dto. G, Buenos Aires, Argentina, So. Amer.
Sakakibara, K., Hitachi Electrical Engineering Works, Hitachi, Ibaraki-ken, Japan

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Balaguer, Manuel M., c/o International Tel. & Tel. Co., 67 Broad St., New York, N. Y.

Bugg, Vernon M., 172 Elm Ave., Rahway, N. J.

Chilofsky, Joseph, 958 N. 7th St., Philadelphia, Pa.

Clark, Bernard, 79 Jenness St., East Springfield, Mass.

Cordier, N. A., 126 Chatterton Pkwy., White Plains, N. Y.

Farnlof, Charles G. T., 1318 Laketon Road, Wilkinsburg, Pa.

Garrison, F. G., Internat'l Tel. & Tel. Corp., Buenos Aires, Arg., So. Amer.

Kamm, J. Lloyd, 1801 N. Lamar St., Dallas, Texas.

McLean, James S., 190 Old Army Road, Scarsdale, N. Y.

Melson, Sydney W., Yeatton Woolrich Road, Abbey Wood, London, S. E. 2, England.

Merrill, J. L., 517 S. Orange St., Media, Pa.

Mountain, C. E., Burma Elec. Supply Co., Mandalay, Burma, India.

McCulloch, G. B., McVie Caterers, Ltd., Sydney, N. S. W., Australia.

Parr, J. C., 245-71st Street, Brooklyn, N. Y.

Pierson, Walter D., 4710 Locust St., Philadelphia, Pa.

Pistorius, L. H., 193 Jeppe St., Johannesburg, South Africa.

Prudham, W. M., 100 Biddle St., Wilkinsburg, Pa.

Schrock, John E., 3720 Main St., Lawrence Park, Erie, Pa.

Stempfle, Frederick, 8126 E. Vernor Highway, Detroit, Mich.

Tate, William, Apartado No. 41, Publa, Mexico.

Voronovsky, T. G., 1162 Waverly Place, Schenectady, N. Y.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during September are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

ESTIMATING BUILDING COSTS. By F. E. Barnes. 3rd ed. N. Y., McGraw-Hill Book Co., 1931. 656 pp., illus., diagrs., charts, tables, 7 x 5 in., cloth, $5.00.——A handbook for contractors and estimators which groups the information needed for determining the amount of labor needed for the various building operations, the current prices of labor and materials, and the cost of replacing buildings built between 1890 and 1926. The data are arranged for quick consultation, usually in tabular form. Labor hours and bills of materials are given. This edition has been thoroughly revised, and new chapters have been added on building insulation, storage silos and circular bins, concrete masonry and cement gun work. The author is Building Valuation Engineer of the New York Central Lines.

DIE CHEMIE DER KOHLE. By W. Fuchs. Berlin, J. Springer, 1931. 510 pp., diagrs., charts, tables, 10 x 6 in., cloth, 45 r. m. ——This monograph summarizes present-day views upon the chemistry of coal, lignite, and peat and is said to cover the literature down to March, 1931. Chapter one treats of the chemical composition of the coal-forming plants and of their decomposition. Chapters two to four treat of peat, lignite, and coal, discussing their petrographic, physical and chemical characteristics, their reaction to chemical and biological agents, behavior when heated, origins, etc. The final chapter gives methods of analysis and discusses their results.

BRONZE UND ROTGUSS, NACH DIN 1705. Berlin, VDI Verlag, 1931. 100 pp., illus., diagrs., charts, tables, 8 x 6 in., paper, 7 r. m. ——Contains the papers and discussions presented at a meeting of the Society of German Engineers devoted to the properties and use of the standard German bronzes and red brasses. The structure and properties of brass and bronze castings, and the standard compositions are discussed, and the experiences of various users are presented. Methods of testing are given. A bibliography for the years 1921 to 1930 is included.

PLASTICITY. Mechanics of the Plastic State of Matter. By A. Nadai with A. M. Wahl, asst. author. Germany. McGraw-Hill Co., 1931. 350 pp., 6 x 9 in., pamphlet. Price $5.00 ($4.00 to members of Founder societies). ——Translated from the German based on the original work of Doctor Nadai (formerly prof. of ap. mech., Univ. of Goettingen, but now with Westinghouse Research Lab.). The original work is amplified by the addition of new information, bringing together the observations of engineers, metallurgists, and physicists, regarding the plastic deformation of metals. It summarizes laws now available for a more exact prediction of stress distribution, and discusses the fundamentals of the theory of plastic flow, especially in metals. This is the first of a series of publications to be prepared by the Engineering Societies Monograph Committee.

PRINCIPLES OF ELECTRICITY. By L. Page and N. I. Adams, Jr. N. Y., D. Van Nostrand, Inc., 1931. 620 pp., illus., diagrs., tables, 9 x 6 in., cloth. $4.25.——Intended for undergraduates who have completed general courses in physics and the calculus, and for advanced students who wish a more comprehensive training in electromagnetism. The ordinary subject matter of electricity and magnetism is treated comprehensively, with unusual space devoted to the phenomena of high-frequency and electromagnetic waves. The book aims to fill the gap between elementary texts and advanced treatises that call for wide knowledge of higher mathematics.

INDUSTRIAL ORGANIZATION. By H. Rubey. Boston & N. Y., Ginn & Co., 1931. 308 pp., diagrs., charts, tables, maps, 9 x 6 in., cloth, $2.80.——A brief but comprehensive course covering such fundamentals of business as promotion, finance, management, organization, marketing, personnel, accounting, estimating, valuation, etc. The book is intended primarily to give the engineer some knowledge of business, in preparation for executive and managerial work; will be useful also to others who wish a general survey of this field.

ALTERNATING CURRENTS. By C. E. Magnusson. 4th edit. N. Y., McGraw-Hill Book Co., 1931. 685 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.——A text-book for undergraduate students which discusses the fundamental principles of the subject and shows their application to industrial problems. The changes in this edition include a rewriting and extension of the chapter on instruments, new chapters on systems of units and symbols, on mercury-arc rectifiers and on hot-cathode rectifiers and oscillators, as well as many new diagrams and illustrations.

ELECTRICAL EQUIPMENT. By H. W. Brown. 2nd edit., N. Y., McGraw-Hill Bk. Co., 1931. 586 pp., illus., diagrs., charts, tables, 9 x 6 in., $5.00.——This text-book is intended to teach students of engineering and others interested in the practical applications of electricity how to apply their knowledge of the theory of operation of electrical machines and the data given in handbooks to the equipping of shops, factories and industrial plants. The requisites of power plants and distribution systems, the characteristics of various motors, generators, transformers, regulating and protective devices, heating and welding apparatus, etc., are discussed and their suitability for various classes of work pointed out.

PROJECTING SOUND PICTURES. By A. Nadell. N. Y., McGraw-Hill Bk. Co., 1931. 265 pp., illus., diagrs., charts, 9 x 6 in., cloth, $2.50.——A book for theater men interested in the reproduction of sound. The principles underlying the mechanisms and circuits used for that purpose are described in a simple, practical manner, and attention is given throughout to the more common troubles of sound apparatus and methods of preventing them.

TECHNICAL WRITING. By T. A. Rickard. 3rd edit. N. Y., John Wiley & Sons, 1931. 337 pp., 8 x 5 in., cloth, $2.00.——Interest in correct speech has become much more widespread since Mr. Rickard's book first appeared in 1919, and many text-books have appeared since that date. His work still remains, however, one of the most readable and best guides to the engineer who wishes to improve his power of expression. It may be recommended heartily. This new edition, prepared for the American Institute of Mining and Metallurgical Engineers, differs from the second edition only in sundry small corrections.

Selected Items From Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Agricultural Machinery

ELECTRIC. Electricity and the Farmer, D. N. McHardy. *Elec. Rev.*, vol. 109, no. 2805, Aug. 28, 1931, pp. 319-320, 1 fig. Critical views by head of engineering department of Harper Adams Agricultural College on present position and future possibilities of application of electricity to agriculture; power for barn machinery and dairy; electricity for heating and cooking; part played by mobile tractor; possibilities of future.

Anemometers

An Anemometer for a Study of Wind Gusts, R. H. Sherlock and M. B. Stout. *Univ. Mich.—Eng. Research Bul.*, no. 20, May 1931, 38 pp., 25 figs. partly on supp. plate. New type of pressure-plate anemometer developed for use in general program of research on loading and strength of overhead lines; equipped with magnetic transmitter and uses oscillograph for recorder; can record accurately average wind velocity over intervals of time as small as 1/8 sec.

Busbars

Structural-Shape Conductors Show Increased Efficiencies, H. W. Papst and D. I. Bohn. *Elec. World*, vol. 98, no. 10, Sept. 5, 1931, pp. 418-419, 3 figs. In order to avoid shortcomings of tubes and bars new type of conductor consisting of structural shapes has been developed; new conductor is designed for currents of about 2,000 to 7,000 amperes at 60 cycles and combines various desirable properties of both tubes and bars; channel conductor ratings are given.

DESIGN. Le calcul des barres omnibus tubulaires aux points de vue mécanique et électrique (Electric Mechanical Strength Calculation of Tubular Busbars), R. Beyaert. *Electricien*, vol. 62, no. 1521, Aug. 1, 1931, pp. 348-353, 2 figs. Simple mathematical analysis with various numerical examples pertaining to aluminum and steel tubular busbars.

Cables

OIL-FILLED. The Theory of Oil-Filled Cable—II, G. B. Shanklin and F. H. Buller. *Gen. Elec. Rev.*, vol. 34, no. 9, Sept. 1931, pp. 523-530, 9 figs. Mathematical theory; loading, and steady-state temperature conditions; thermal transients; operational equations for transient temperatures; solution of operational equations; oil demand; systems of oil feed and reservoir characteristics.

RESERVOIRS. Oil-Pressure Reservoirs for Underground Cables, T. C. Aitchison. *Gen. Elec. Rev.*, vol. 34, no. 7, July 1931, pp. 410-415, 20 figs. Oil-pressure reservoirs are considered essential to successful operation of oil-filled and solid cables above 25 kv.; principal functions; various equipment and accessories are illustrated and described.

TELEPHONE. Securing Freedom from Cable Trouble, R. R. Rex. *Telephony*, vol. 101, no. 10, Sept. 5, 1931, pp. 30-31. Some helpful suggestions for securing freedom from telephone man's imaginary cable trouble; importance of periodic inspection and accurate records; discussion of causes of cable failure; suggested methods for locating trouble.

TESTING. The Electrical High-Pressure Testing of Cables and the Localization of Faults, J. Urmstom. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 416, Aug. 1931, pp. 983-1003 and (discussion) 1004-1012, 35 figs. Electrical high-pressure testing of cables, immediately after installation is completed, is discussed; author concludes that high-pressure d-c. test is useful and fulfils ordinary requirements; new connection for high-pressure d-c. testing set is described; methods of localization of more difficult kinds of faults are given; these show that there are very few faults which cannot be fairly accurately located.

UNDERGROUND MANHOLES. High-Pressure Manhole Washing Saves Expense of Opening Drains, C. B. Sharp. *Elec. World*, vol. 98, no. 7, Aug. 15, 1931, pp. 283-284, 1 fig. Forty plugged manhole drains was average per month reported on underground system of Detroit Edison Co. when manholes were being cleaned by hand; number has been reduced to 28 through use of water at 120-lb. pressure supplied from tank truck; also cleaning is done better, quicker and with fewer men.

Case Hardening

CARBURIZING. A New Method of Case-Hardening in an Electric Furnace. *Mar. Engr. and Motorship Bldr.*, vol. 54, no. 648, Sept. 1931, p. 351, 1 fig. Equipment introduced into England by Wild-Barfield Electric Furnaces, Ltd.; description of process, with costs of operation.

Cavitation

HYDRAULIC TURBINES. Cavitation of Large Turbine Runners, A. S. Robertson. *Elec. News*, vol. 40, no. 16, Aug. 15, 1931, pp. 35-36 and 38, 3 figs. Average maintenance costs amount to about $450 per runner per year using electric arc welding.

Circuit Breakers

TESTING. Testing Breaker Insulation by Power-Factor Methods, F. C. Doble. *Elec. World*, vol. 98, no. 9, Aug. 29, 1931, pp. 374-375. Author is reviewing work done by his organization in testing about 14,000 bushings and analyzing circuit-breaker insulation conditions by power factor method as applied to 11-kv. to 150-kv. equipment, and stressing advantages of a-c. test as compared with d-c. procedure and discussion by C. L. Dawes and C. A. Adams of Harvard, C. A. Powel of Westinghouse Electric & Manufacturing Co. and other outstanding men of electric manufacturing and power supply industry.

Circuits

ELECTRIC. Mathematical Analysis of Non-linear Circuits—I, A. Boyajian. *Gen. Elec. Rev.*, vol. 34, no. 9, Sept. 1931, pp. 531-537, 7 figs. In recent years, both troublesome problems and useful applications of networks with non-linear branches have been rapidly increasing, calling for more thorough and comprehensive analysis of phenomena involved; although physical or graphical analysis may prove sufficient for purpose, yet whenever possible mathematical analysis is highly desirable; more important non-linear circuits are: saturating circuits, arc circuits, and thermionic circuits; purpose of study is to develop technique that is applicable to all such circuits.

Transients in Grounded Wires Lying on the Earth's Surface, J. Riordan. *Bell System Tech. Jl.*, vol. 10, no. 3, July 1931, pp. 420-431, 4 figs. Voltages during transient conditions in grounded wire lying on earth's surface due to current in second grounded wire also on earth's surface are formulated for types of transient currents ordinarily obtained in a-c. and d-c. circuits; fundamental formula is for voltage due to unit step current, that is, current zero for time less than zero, and unity for time greater than zero; curves are given for function determining this voltage for wide range of values of its two parameters.

Conductivity

METALS. The Problem of the Electrical Conductivity of Metals, C. D. Niven. *Can. Jl. Research*, vol. 5, no. 1, July 1931, pp. 79-86. It is pointed out that mathematicians in their attempts to form theories of electrical conduction, do not lay emphasis on fact that at low temperatures, resistance, as a rule, does not vanish; in those cases in which it does, it vanishes suddenly; in view of this, question arises as to whether right model for conductivity metal is visualized; it is suggested that fundamentally a metallic atom is one in which electron configuration is incomplete.

Cooling

TURBO-GENERATORS. Hydrogen-Cooled Generators Have Economic Merit, M. D. Ross. *Elec. World*, vol. 98, no. 10, Sept. 5, 1931, pp. 403-409, 3 figs. In design of large turbo-generators next major step will be adoption of hydrogen gas as cooling medium; hydrogen is desirable as it has somewhat better heat transfer properties than helium, lower density and is available commercially at relatively low cost; density of commercial hydrogen is about 8 per cent that of air, so that windage losses, which are relatively high in turbo-generators, are reduced to negligible figure.

Dielectrics

TESTING. Dielectric Phenomena at High Voltages, B. L. Goodlet, F. S. Edwards and F. R. Perry. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 414, June 1931, pp. 695-727 and (discussion) 727-735, 36 figs. Breakdown of air, oil and solid dielectrics by normal-frequency impulsive and high-frequency voltages; large amount of original numerical data is given, covering entire range of voltage up to 1 million volts.

Education

ENGINEERING. Technical Education, H. L. Guy. *Engineering*, vol. 132, no. 3422, Aug. 14, 1931, pp. 201-202. Editorial comment on address before Oxford Summer School; author presses earnestly for closer correlation between works and technical schools; he suggests that summer school provides, perhaps easiest plan of any for keeping technical colleges in touch with practical problems.

RESEARCH. The Function of Research in Engineering Education, D. C. Jackson. *Science*, vol. 74, no. 1912, Aug. 21, 1931, pp. 183-187. Research not only has function in engineering education, but is integral part of properly conceived engineering education; investigatory spirit and achievement are more important attributes for engineering teacher than higher degrees; spirit for establishing research laboratories and foundations in engineering schools is presage of good educational spirit in schools. Before Soc. Promotion Eng. Education.

Electric Drive

COAL PREPARATION PLANTS. Electrification Problems in Modern Preparation Plants—I and II, E. J. Gealy. *Coal Age*, vol. 36, nos. 7 and 9, July 1931, pp. 346-348 and Sept., pp. 477-478 and 482, 3 figs. July: Review of development in design and construction; importance of observing certain fundamental principles; standardization of equipment. Sept.: Choice of motors, motor starters, pushbutton control, safety switches, power factor, welding, and lighting.

PUMPS, CENTRIFUGAL. Some Notes on Electrically Driven Centrifugal Pumps, H. E. Beckwith. *Am. Water Works Assn.—Jl.*, vol. 23, no. 8, Aug. 1931, pp. 1120-1127. Characteristics of inadequate installations; rapid method of checking pump efficiency; table of gallons of water delivered per kw-hr. against various heads on assumption that pump and motor are 100 per cent efficient; results of checking efficiency; measuring output of water.

Electrolysis

The Preparation of Organic Compounds by Electrolytic Methods—IV, S. Glasstone. *Indus. Chemist*, vol. 7, no. 79, Aug. 1931, pp. 315-317. Chemical and electrochemical halogenation; electrochemical chlorination; manufacture of bromoform and iodoform; chloroform and chlorhydrin; electrochemical diazotization.

Engineers

SALARIES. Relation Between an Engineering Education and Income, J. D. Beatty. *Indus. and Eng. Chem.*, vol. 23, no. 9, Sept. 1931, pp. 1070-1074, 6 figs. How salaries of engineers compare with salaries of men in other professions; what groups in engineering profession receive best salaries; how salaries of engineering graduates of Carnegie Institute of Technology compare with salaries of graduates from other engineering institutions generally.

Frequency

STANDARDIZATION. Frequency Standardisation. *Engineer*, vol. 152, no. 3941, July 24, 1931, p. 96. When general interconnection was deemed to be desirable problem of frequency standardization presented itself, but it remains to be seen whether widespread interconnection will prove great boon; on frequency standardization alone very large amount of money is being spent.

Furnaces

ANNEALING. Applications of the Electric Furnace for Non-Ferrous Metals With Special Reference to the Bright Annealing Process, H. C. Kloninger, G. Keller and H. Meuche. *Inst. Metals—Advance Paper*, no. 575, for mtg. Sept. 14-15, 1931, 18 pp., 12 figs. Main types of furnaces used for bright-annealing process; during past few years considerable improvements have been made in quality of product as well as in simplifying handling of annealed metals.

ARC. Twenty Year Advance in Electric Arc Furnaces for the Production of Iron and Steel, W. E. Moore. *Electrochem. Soc.—Preprint*, no. 60-11, for mtg. Sept. 2-5, 1931, pp. 65-78. In period of two decades electric arc melting furnace has made wonderful progress, having increased in number 65 times, in maximum size per heat five times, in maximum daily capacity 10 times, and power consumption per unit ton output has been decreased from 600-800 to 400-600 kw-hr.; carbon electrode consumption decreased from 30-40 lb. (14-18 kg.) down to 8-15 lb. (3.6-6.8 kg.).

ELECTRODES. The Soderberg Electrode, Oblong Electrodes and Other New Developments, M. Sem. *Electrochem. Soc.—Preprint*, no. 60-20, for mtg. Sept. 2-5, 1931, pp. 199-210, 4 figs. Electric furnace engineers originally objected to round cross section Soderberg electrode; they were convinced that oblong or rectangular electrodes were essential for efficient furnace operation; oblong electrodes produce larger active hearth, and gases evolved during furnace operation are more evenly distributed through charge; however, round electrodes are often to be preferred on account of certain electrical features and advantages.

HEAT TREATING. Electricity Used on a Large Scale for Heat Treating, G. Coley. *Iron Age*, vol. 128, no. 12, Sept. 17, 1931, pp. 747-751, 8 figs. Description of heat-treating furnaces; pig iron from blast furnaces and cupolas is duplexed with electric furnaces for making iron castings, at plant of Ford Motor Co.

INDUCTION. Tonnage Melting by Coreless Induction—VI, E. F. Northrup. *Fuels and Furnaces*, vol. 9, no. 9, Sept. 1931, pp. 1067-1071, 1 fig. Various classifications under which coreless induction melting may be considered; use of coreless induction furnace as refining furnace and ladle; future of industrial melting.

INDUSTRIAL. Heat Treating, Forging and Melting with Electricity, G. Coley. *Iron Age*, vol. 128, no. 11, Sept. 10, 1931, pp. 678-683 and 721, 12 figs. Equipment and procedure at plant of Ford Motor Co. with connected load of 85,000 kw., electric furnaces for duplexing blast-furnace and cupola iron in foundry, and indirect arc furnaces in brass foundry.

Fuses

ELECTRIC. Fuse Performance in Relay Service, H. D. Braley. *Power*, vol. 74, no. 6, Aug. 11, 1931, pp. 200-201. Test results show how accurate fuses of same size are in time of interrupting overload, how sensitive they are to load changes, and how selective two or more fuses, of different sizes in series, are in clearing fault on power systems.

Gases

CONDUCTIVITY. The Conductivity of Gases in Uniform Electric Fields, S. P. McCallum. *Lond. Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol. 12, no. 76, Aug. 1931, pp. 384-392. In many recent publications various theories of electrical discharge have been elaborated which are based on hypotheses of doubtful validity; attention is drawn to objections that have already been raised to these theories, and results are compared with results of experiments on monatomic gases which have recently been made at Electrical Laboratory, Oxford.

Generators

GROUNDING. The Effects on Noise Induction of Grounded Neutral Generators. *Nat. Elec. Light Assn.—Pub.*, no. 153, Aug. 1931, 4 pp. Results of investigations of effects on noise frequency induction of grounded neutral generators feeding directly on line; nature and source of difficulties experienced are explained and several possible remedial measures are described.

Grid Glow Tube

CONTROL. Application of the Grid-Glow Tube to Oil Burner Control, J. P. Kriechbaum, J. V. Breisky and T. Draper. *Oil Heat*, vol. 4, no. 9, Sept. 1931, pp. 11-12 and 66, 2 figs. Design, construction and operating features of Protecto Glow System; oil burner safety devices.

Harmonics

MEASUREMENTS. Measuring Voltage Harmonics, E. Heuter. *Elec. Rev.*, vol. 109, no. 2804, Aug. 21, 1931, pp. 280-281, 4 figs. Instrument described depends on simple application of resonance principle and enables magnitude of voltage harmonics to be measured directly.

Heating

GREENHOUSES. Electrically Heated Greenhouse, G. N. Hawley. *Elec. World*, vol. 98, no. 8, Aug. 22, 1931, pp. 322-323, 2 figs. Electric heating of greenhouse at Riverside, Calif., has proved so successful that another new and profitable field for industrial heating has been opened to power company and nurserymen are able to make 75 per cent saving in investment for heating equipment.

RAILROAD SHOPS. Railroad Saves Six Times Electric Heat Cost, W. S. Scott. *Elec. World*, vol. 98, no. 10, Sept. 5, 1931, pp. 423-427, 3 figs. Study was made of major heat-treating operations in repair shops of Norfolk & Western Railway, and figures arrived at, and agreed upon, as conservatively representing annual savings by virtue of electric heating; power cost $17,805 in one year and savings credited to its use in electric heat amount to more than $100,000.

Hydroelectric Plants

AUTOMATIC. The Upper Notch Automatic Hydro-Electric Power Plant, R. F. Legget, P. J. Croft, J. R. Desloover. *Eng. Jl.*, vol. 14, no. 8, Aug. 1931, pp. 437-444, 12 figs. Plant located on Montreal river, 15 mi. southeast of Cobalt, northern Ontario; equipment consists of two 48-ft. head, 6,500-hp. 125-r. p. m. turbines, and two 6,500-kva., 11,000-volt, 25-cycle generators; switchgear and control equipment are fully automatic and are designed for possible remote control from distant point; switchgear is of metal clad type; station output transformed to 110,000 volts by three 4,500-kva. transformers and is fed into extensive network by means of line 32.7 mi. long.

INTAKES. Recent Applications of Draft Distributors to Power Plant Intakes, H. G. Acres. *Eng. News-Rec.*, vol. 107, no. 11, Sept. 10, 1931, pp. 403-410, 13 figs. Rational design of intakes long neglected; studies made for Queenston-Chippawa plant in Canada led to development of Johnson-Wahlman draft distributor; four intakes designed to meet diverse conditions; elements of ideal intake design; intake of Chelan development of Washington Water Power Co. of Spokane; 14 ft. and 17 ft. in diam.; intake for St. John River Power Co. at Grand Falls, New Brunswick; delivers 7,500 sec. ft.; design of intake for projected development of 10,000- to 12,000-sec. ft. capacity.

Illuminating Engineering

RUSSIA. Progress in Illuminating Engineering in the U. S. S. R., Slokhay-Natalchenko. *Illum. Engr.*, vol. 24, Sept. 1931, pp. 220-222, 4 figs. During period 1921-30 illuminating engineering has made great progress in U.S.S.R.; vital part played by illumination is now recognized fact; good lighting is regarded as important in all branches in industry, and especially as means of improving safety and health; there are quite a number of laboratories interested in illumination in Leningrad, Kharkov, Moscow and other cities; notes on Illumination Congress of U.S.S.R.

Industrial Plants

ELECTRIC CONTROL. Centralized Control for Aggregate Plant, L. F. Leurey. *Elec. West.*, vol. 67, no. 3, Sept. 1, 1931, pp. 120-123, 8 figs. Electric operation of modern sand and gravel plant of Kaiser Paving Co., Pleasonton, Calif.; raises operating efficiency through reducing starting time and labor costs.

ELECTRIC POWER. Distributing the Electric Energy, R. G. Hornberger. *Maintenance Eng.*, vol. 89, no. 8, Aug. 1931, pp. 381-384, 3 figs. Review of design fundamentals of distribution system in industrial plant; typical wiring layouts.

Industrial Electrification—I and II, R. H. Wilmot. *Elecn.*, vol. 107, nos. 2775 and 2777, Aug. 7, 1931, pp. 186-189 and Aug. 21, pp. 247-249, 6 figs. Numerous advantages of electrical drive; use of a-c. or d-c. supply; private power generation or public power supply; mechanical *vs.* electrical drive; comparison of costs is given in numerical examples.

Insulating Materials

PORCELAIN. Mechanical and Thermal Shock Tests on Cermic Insulating Materials, H. M. Kraner and R. A. Snyder. *Am. Ceramic Soc.—Jl.*, vol. 14, no. 9, Sept. 1931, pp. 617-623, 3 figs. Simple tests, as developed for daily production of electrical porcelain; laboratory tests and results for number of ceramic insulating materials; from these it is shown that mechanical strength and resistance to thermal shock are valuable indications of mechanical properties of bodies and glazes; results obtained in testing foreign and American-made porcelains are compared.

The Effect of Firing Temperature on the Dielectric Strength of Porcelain, A. J. Monack and L. R. Shardlow. *Am. Ceramic Soc.—Jl.*, vol. 14, no. 9, Sept. 1931, pp. 603-607, 5 figs. Electrical porcelain body was fired to various cone temperatures and puncture voltages were determined; data from tests in which number of specimens used was sufficiently large to give mean values with small probable errors.

Insulating Oil

Report of Insulating Oils. *Int. Electrotech. Commission—Report of mtg. Advisory Committee*, no. 10, Stockholm, June-July, 1930. Documents from Canada, France, Germany, Great Britain, Holland, Italy, Japan, Norway, Switzerland, Sweden, and United States, in their respective languages.

Insulators

TESTING MACHINES. Testing Machine for Insulators. *Engineering*, vol. 132, no. 3420, July 31, 1931, pp. 130-132, 7 figs. Testing machine, installed in high-tension laboratory of General Electric Co., enables insulators to be subjected to longitudinal and transverse stresses while exposed to electric pressure; made by W. and T. Avery; it is suitable for testing insulators of either post or string types, and can be used for tension or torsion tests, or for combination of two, and also for combined tension and vibratory test, up to maximum load of 24,000 lb

Lamps

GLOW. Gaseous Discharge Tubes. *Elecn.*, vol. 107, no. 2778, Aug. 28, 1931, pp. 273-275, 8 figs. Ripple neon; possibilities of hot cathode lamp; neon tubes as plant stimulant; actual photographs of various forms of blue ripple discharge; photographs of neon ripple and striated discharge; hot cathode lamp circuit for single phase a-c. supplies; and for three-phase supplies; characteristic of hot cathode tube.

Light and Lighting

Brightness Contrasts Determine Visual Efficiency, M. Luckiesh. *Elec. World*, vol. 98, no. 7, Aug. 15, 1931, p. 280. Although it is impractical to present complete table of brightness contrasts encountered in seeing, number of typical examples which have wide application have been selected for purpose of illustration, are given.

STREET. The Evaluation of Glare in Street-Lighting Installations, W. S. Stiles. *Illum. Eng.*, vol. 24, Aug. 1931, pp. 187-189, 4 figs. Maximum permissible glare; glare curves of center suspension and staggered suspension systems; elimination of glare from distant lamps; methods of calculation elucidated in appendix. (Concluded.)

Lightning Protection

SIGNALS AND SIGNALING. Lightning on Signal Power Lines, O. L. Jones. *Ry. Signaling*, vol. 24, no. 8, Aug. 1931, pp. 276-279, 4 figs. Results of certain field and laboratory analyses of lightning disturbances on signal power transmission lines; wiring diagram of signal power circuit. Bibliography.

Loud Speakers

Means for Radiating Large Amounts of Low Frequency Sound, E. W. Kellogg. *Acoustical Soc. Am.—Jl.*, vol. 3, no. 1, pt. 1, July 1931, pp. 94-110, 3 figs. Principals and possibilities of electroacoustic device of large radiating power are discussed; consideration of possible types of loud speaker with large area single diaphragm with baffle; large area composed of multiple units, with baffle; multi unit, short horn construction; long horn type, one or several unit; siren type with horn.

Magnetic Alloys

PROPERTIES. Some Magnetic Alloys and their Properties, H. H. Potter. *Lond. Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol. 12, no. 76, Aug. 1931, pp. 255-264, 4 figs. One of most striking physical properties of element manganese is its tendency to form in conjunction with other non-ferromagnetic elements binary and ternary alloys which show pronounced ferro-magnetism; complete analysis of magnetic properties of binary and ternary alloys conveying manganese is given.

Magnetic Hardening

METALS. Hardening Metals by Rotating Magnetic Fields, E. G. Herbert. *Metallurgia*, vol. 4, no. 20, June 1931, pp. 47-50, 10 figs. Precession theory of hardening; graphs illustrating results of experimental work, leading to new conception of philosphy of hardening, including quench-hardening, work-hardening, age-hardening, and hardening of work-hardened metals by low-temperature annealing. Bibliography.

Measurements

Precision Measurements of Alternating Currents Up to 2,000 Amperes, A. H. M. Arnold. *Jl. Sci. Instruments*, vol. 8, no. 5, May 1931, pp. 154-155. Figures are given of performance of current transformer with nickel iron core, having ratio 2,000/1, operating on burden of 100 volt-amperes at rated current; ratio is within 3 parts in 10,000 of its nominal value in frequency range 25 cycles per sec. to 100 cycles per sec. at full current to one-tenth of full current; in conjunction with non-inductive resistance of accurately known value and electrostatic voltmeter, transformer may be used for measuring currents up to 2,000 amperes with accuracy of few parts in 10,000.

Measuring Instruments

SPECIFICATIONS. Report on Electrical Measurement Instruments. *Int. Electrotech. Commission—Report of mtg. Advisory Committee*, no. 13, Stockholm, June-July 1930. Documents from Argentina, Germany, Italy and United States in their respective languages.

Mica

ELECTRIC PROPERTIES. Some Electrical Properties of Foreign and Domestic Micas and the Effect of Elevated Temperatures on Micas, A. B. Lewis, E. L. Hall and F. R. Caldwell. *U. S. Bur. Standards—Jl. Research*, vol. 7, no. 2, Aug. 1931, pp. 403-418, 8 figs. Number of samples of mica, fairly representable of major sources of world's supply, were tested for dielectric constant, power factor, dielectric strength, and ability to withstand elevated temperatures; results.

Motors

ALTERNATING CURRENT. A-C. Commutator Motors. *Elec. Rev.*, vol. 109, no. 2805, Aug. 28, 1931, pp. 323-324, 7 figs. Widespread adoption of a-c. has resulted in paying of increased attention to variable-speed a-c. three-phase motors; shunt performance curves of motor with series characteristics are given.

ENCLOSED. Enclosed Electric Motors. *Engineer*, vol. 152, no. 3943, Aug. 7, 1931, p. 152, 4 figs. Motors designed by Lancashire-Dynamo Motor Co., Trafford Park, Manchester, to meet adverse conditions; one of them is totally enclosed machine primarily designed for gas works; other is totally enclosed frame-cooled machine, known as "Tefeo" motor; it is standard Lancashire squirrel-cage or slip-ring machine, fitted with internal end shields and special end covers.

FRACTIONAL HORSEPOWER. Voltage Relations and Losses in Small Universal Motors, A. F. Puchstein and I. S. Campbell. *Ohio State Univ. Studies—Eng. Experiment Station—Bul.*, no. 58, Jan. 1931, 27 pp., 24 figs. Importance of data on universal motors; general test results and conclusions; apparatus arrangement and test methods used; determination of losses; voltage-vector test data and results; motor-loss test data and results. Bibliography.

SPEED REGULATION. Speed Regulation of Alternating-Current Motors, G. W. Stubbings. *Mech. World*, vol. 90, no. 2330, Aug. 28, 1931, pp. 196-198, 2 figs. Three principal methods of speed control discussed are pole changing, rheostatic control of rotor resistance, and use of commutator.

SYNCHRONOUS. New Synchronous Motor for High-Torque Loads, R. S. Wright. *Elec. World*, vol. 98, no. 8, Aug. 22, 1931, pp. 320-322, 6 figs. Design engineers worked for several years to perfect motor having desirable running characteristics of standard synchronous motor yet capable of developing high starting and pull-in torque with low starting current; result of these investigations has been development of new low-speed (450 r. p. m. and below) motor which has mechanical simplicity and is highly efficient.

Networks

FAULT RECORDERS. Der Siemens-Stoerungschreiber (Siemens' System Disturbance Recorder), W. Hofmann and P. M. Pflier. *Siemens Zeit.*, vol. 11, no. 7, July 1931, pp. 325-333, 12 figs. Analytical review of various types and their characteristics; new three-phase automatic recorder of Siemens' and Schuckert, and its testing; test data are given in curves and tables.

PROTECTION. Relay Study for the Application of Impedance Relays to Ground Fault Protection, L. S. C. Tippett. *Instn. Engrs. Australia—Jl.*, vol. 3, no. 7, July 1931, pp. 233-243, 16 figs. Method of applying theory of symmetrical components to analysis of performance of impedance relays of conventional design when used for protection against ground faults; as preliminary to this method of determining correct impedance networks of any given system is discussed, under various operating conditions; application is made to portion of Victorian State Electricity Commission's system which gives ample illustration of principles involved.

Photoelectric Cells

Recent Contributions to Light Valve Technic, O. O. Ceccarini. *Soc. Motion Picture Engrs.—Jl.*, vol. 17, no. 3, Sept. 1931, pp. 305-320 and (discussion) 320-325, 15 figs. Structural changes made in light valves with object of improving their quality, stability of operation, and efficiency, most important being introduction of damping to off-set resonance; these features are chiefly considered from standpoint of production requirements and engineering economies; new synchronous slit type oscillograph permitting study of behavior of valve is described.

Ionization in Gas-filled Photoelectric Cells: The Inert Gases in Coesium on Silver Photoelectric Cells, and Time Lag in Gas-filled Photoelectric Cells, W. F. Tedham. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol.12, no. 76, Aug. 1931, pp. 224-232, 8 figs. Some uncertainty appears to exist as to best gas-filling in use in photoelectric cells which are sensitive to visible or infra-red light; in view of this uncertainty, question of relative advantages of helium, neon, and argon, and also krypton and xenon as gas-fillings in photoelectric cells were reinvestigated in some experiments.

Power Factor

IMPROVEMENT. The Correction of Low Power Factor, J. Leech-Porter. *Can. Min. Jl.*, vol. 52, no. 24, July 1931, pp. 616-618, 3 figs. Various methods for improvement of power factor conditions in industrial plants using induction motors for drive; methods for calculating returns, *i. e.*, first cost; operating costs; gross returns; net returns; points to investigate; application of methods shown for case of motorcycle company employing 104 motors ranging from 1 to 150 hp. with total rating of 1,850 hp.

Power Industry

GOVERNMENT CONTROL. Socialization or Private Enterprise, W. H. Onken, Jr. *Elec. West*, vol. 67, no. 3, Sept. 1, 1931, pp. 110-111. In reality, experience proves that notwithstanding all advantages possessed by governmental undertaking, private enterprise, in this case electric light and power corporation, more often than not renders better service at less cost; this is due to two outstanding and very obvious disadvantages of governmental enterprises, *i. e.*, political interference in operation of project and lack of incentive.

RATE MAKING. Regulation by Conference Versus Formal Rate Proceedings, L. O. Whitsell. *Elec. West*, vol. 67, no. 3, Sept. 1, 1931, pp. 108-110. Author brings to bear six years of experience in regulation by proposing that informality replace formality in rate matters and that utilities take voluntary action which will make them largely self-regulating. Before Pac. Coast Elec. Assn.

UNITED STATES. The Electric Light and Power Industry, Basic Statistical Data. *Nat. Elec. Light Assn.—Statistical Bul.*, Aug. 1931, 39 pp. Statistics contained in report embrace operations of enterprises devoted exclusively to generation and distribution of electricity, plus electric departments of all others which maintained electric light and power systems jointly with other public utility services; data were determined from reports received at N. E. L. A. headquarters from some 400 companies, whose operations represented approximately 92 per cent of entire industry.

Power Supply

SERVICE INTERRUPTION. Service Interruption for Repairs Should be Announced, H. A. Martin. *Elec. World*, vol. 98, no. 9, Aug. 29, 1931, p. 367. When extensive prearranged interruptions are necessary over period of several days, notice should be placed in newspaper in town being served that service will be interrupted and this notice should state why interruption is necessary and give definite schedule of hours and dates during which no service may be expected.

Radio

MEASURING INSTRUMENTS. Use of Automatic Recording Equipment in Radio Transmission Research, P. A. de Mars, G. W. Kenrick and G. W. Pickard. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 9, Sept. 1931, pp. 1618-1633, 10 figs. Apparatus developed for low-frequency (17.8 kc.), intermediate-frequency (770 kc.), and high-frequency (6942.5 kc.) field-intensity recording; circuits employed are discussed with particular reference to expedients for obtaining nearly logarithmic scales when used with Leeds and Northrup recording potentiometer.

RECEIVING APPARATUS — NOISES. Noise Generation Within Radio Receivers, R. de Cola. *Radio Eng.*, vol. 11, no. 8, Aug. 1931, pp. 15-17, 7 figs. Theoretical discussion of radio receiver design as related to employment of new type tubes; noises resuming from thermal agitation; shot effect; and secondary emission and ionization; thermal agitation. Before Inst. Radio Engrs.

Railroads

ELECTRIC CONTROL. La régulation par unités multiples et l'automatisme dans la marche des motrices électriques (Multiple Control and Automatic Control in Operation of Electric Driven Vehicles), L. Barbillion. *Technique Moderne*, vol. 23, no. 15, Aug. 1, 1931, pp. 517-524, 13 figs. Fundamental principles, diagram showing automatic control by reversing controller system Sprague; control by contactors of powerful modern units; Thomson Houston system; electropneumatic control of Westinghouse; use of camshaft; Sprague Thomson system as used on Paris subway with wiring diagram; Jeumont-Heidman system on same railroad.

SUBSTATIONS. Heavy-Duty Rectifiers and Their Application to Traction Substation, J. W. Rissik and H. Rissik. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 416, Aug. 1931, pp. 933-963 and (discussion) 963-982, 23 figs. As result of special problem associated with supply of d-c. to traction systems, as distinct from lighting and power systems, automatic substations technique has advanced in two widely diverging directions; whereas modern substation practise in America is characterized by almost exclusive use made of rotary convertors, European practise favors adoption of mercury-arc rectifiers; present state of development of iron-clad rectifier and its application to traction supply as reflected in more recent converting installations on Continent.

Crawler Cranes Solve Problem in Railroad Electrification, T. J. Skillman. *Elec. World*, vol. 98, no. 9, Aug. 29, 1931, p. 371, 1 fig. Erection of steel for substation, tower and miscellaneous purposes in railroad electrification work sometimes proves difficult for structures not sufficiently close to main railroad tracks to permit handling by locomotive crane; here crawler cranes have proved their value in convenience and economies.

Rating

ELECTRIC MACHINERY. Report on Rating. *Int. Electrotech. Commission—Report of mtg. of Advisory Committee*, no. 2, Stockholm, June-July, 1930. Documents from Austria, France, Germany, Japan, Poland, Sweden, Switzerland, and United States, in their respective languages.

Reactive Power

METERING. Reactive Kva. Metering—IX, E. O. Goodale. *Elec. West*, vol. 67, no. 3, Sept. 1, 1931, pp. 116-117, 5 figs. Two-element three-phase meters do not give accurate results on four-wire circuits under normal conditions.

Reactors

Design of Standards of Inductance, and the Proposed Use of Model Reactors in the Design of Air-Core and Iron-Core Reactors, H. B. Brooks. *U. S. Bur. Standards—Jl. Research*, vol. 7, no. 2, Aug. 1931, pp. 289-328, 10 figs. Useful general relations concerning self and mutual inductance of geometrically similar coils are presented and their usefulness is demonstrated.

Rectifiers

COPPER OXIDE. Metal Rectifier Applications. *Engineer*, vol. 152, no. 3947, Sept. 4, 1931, pp. 241-248, 15 figs. Best-known applications are those associated with wireless reception; but this simple method of rectification is applicable in many other directions, and currents and voltages considerably greater than those heeded for wireless reception can be dealt with.

Regulators

INDUCTION. The Application of Induction Regulators, V. C. Bryan. *Elec. Rev.*, vol. 109, no. 2805, Aug. 28, 1931, p. 316, 4 figs. Fundamental principles of apparatus which is not so generally understood, either in theory or in application.

Remote Control

POWER PLANTS. Remote-Control Switchgear at Woolwich. *Engineer*, vol. 152, no. 3940, July 17, 1931, p. 76, 3 figs. Installation of remote electrically controlled switchgear put into service at Bellwater Gate power station of Woolwich Borough Council; switchgear is designed for pressure of 6,600 volts and is electrically operated by remote control from corresponding panels on main control board situated in central position in station; cubicles are built up of molded stonework slabs reinforced by steelwork.

SIGNALS AND SIGNALING. Chicago Great Western Saves $7,000 Annually by Remote Control of Tunnel Interlockings. *Ry. Age*, vol. 90, no. 22, May 30, 1931, pp. 1071-1072, 3 figs. Increased safety and flexibility of operation, and high return on investment have amply warranted expenditure of $18,000; solution of problem; operation of system; color light signals and dual control switch machines; economies effected.

Resistors

DESIGN. The Design and Construction of a Shielded Resistor for High Voltages, R. Davis. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 416, Aug. 1931, pp. 1028-1035, 2 figs. Design of shielded resistor for use at voltages up to 60 kv.; considerations governing design are discussed in detail; construction and performance of resistor are dealt with and finally question of extending further range of such apparatus is touched upon.

Rotors

Dead Points in Old Rotors, W. L. Hurlburt. *Elec. West*, vol. 67, no. 3, Sept. 1, 1931, p. 123, 1 fig. When modernizing control equipment of some old wound-rotor induction motors equipped with slip rings and external starting resistance, dead points often develop at start if resistance is removed; leakage flux conditions should be observed.

TURBO-GENERATORS. Stresses in Retaining and Centering Rings for Turbine-Generator Rotors, R. Patterson and D. H. Harms. *Applied Mechanics (A.S.M.E. Trans.)* vol. 53, no. 9, May-Aug. 1931, pp. 79-87 and (discussion) 87-89, 10 figs. Paper before Am. Soc. Mech. Engrs., indexed Engineering Index 1930, p. 1829, from Advance Paper, no. 42, for mtg. Dec. 1-6, 1930.

Switchgear

STANDARDIZATION. A Discussion of New Standards for Switching Equipment and Insulator Units as Adopted by N.E.M.A. *Elec. Light and Power*, vol. 9, no. 9, Sept. 1931, pp. 27-29, 2 figs. Rated voltage; determination of flashover values corresponding to preferred voltage ratings; curve showing minimum wet and dry flashover values for assembled, upright, base-mounted insulators; correction factors for apparatus rated on basis of varying altitudes; theoretical minimum safe distances to ground for various voltages at 60 cycles; spacing of insulator columns for various voltages.

Telephone Relays

Characteristics of Strowger Relays, R. W. Graybill. *Telephone Engr.*, vol. 35, no. 8, Aug. 1931, pp. 25 and 28, 5 figs. Discussion of features of horizontal relay structure which may be varied to secure different performance characteristics and which account for long life of this type of relay.

Television

Television, E. H. Felix. N. Y., McGraw-Hill Book Co., 1931, 272 pp., illus., diagrs., charts, $2.50. Book explains basic processes involved in any television system and describes methods of existing systems; standards of performance requisite to commercial service are outlined, and limitations of existing methods are pointed out; gives good general survey, in not too technical language, of present situation, problems that television faces, and its probable future. Eng. Soc. Lib., N. Y.

RECEIVING APPARATUS. Standards of Performance for Commercial Television Receivers, C. H. W. Nason. *Radio Eng.*, vol. 11, no. 8, Aug. 1931, pp. 30 and 45, 2 figs. Television receiver design as distinguished from radio sound receiver design; typical selectivity curve; sensitivity characteristics and fidelity curves for television receiver.

DESIGN. The Design of a Complete Television System, C. E. Huffman. *Radio Eng.*, vol. 11, no. 8, Aug. 1931, pp. 36 and 38, 10 figs. Technical information of direct use to radio engineers who desire to master elements of television. Before Radio Club.

Testing Laboratories

MANUFACTURING PLANTS. Baltimore's High Voltage Laboratory, D. H. Rowland. *Baltimore Engr.*, vol. 6, no. 5, Aug. 1931, pp. 9-11 and 16, 6 figs. High voltage laboratory of Locke Insulator Corp., makes available to electrical industry facilities which are of greatest importance in considering future growth of electrical transmission; laboratory is capable of producing 2,500,000 volts; equipment is briefly described. Before Am. Inst. Elec. Engrs.

Transformers

OSCILLATIONS. Transformer Oscillations Caused by Damped Oscillatory Waves, L. V. Bewley. *Gen. Elec. Rev.*, vol. 34, no. 9, Sept. 1931, pp. 512-517, 8 figs. Purpose of article is to consider possibilities of building up excessive internal oscillations in transformers by means of damped oscillatory incident waves, and in particular to show effects of transformer losses and decrement of applied wave in limiting these abnormal internal voltages.

Transmission Lines

DESIGN. On the Determination of Stringing Tensions for Transmission Lines and Cables, J. W. Campbell. *Eng. Jl.*, vol. 14, no. 9, Sept. 1931, pp. 477-481. Method for finding temperature-tension relations for suspended cables; of single spans with points of support at same level, single spans with points of support at different levels, composite spans which have intermediate supporting structures; hyperbolic methods are used throughout, validity of method for sage of any magnitude is shown.

HIGH TENSION. The Louisville-Cincinnati Interconnection, H. W. Eales. *Elec. Light and Power*, vol. 9, no. 9, Sept. 1931, pp. 30-34, 13 figs. Since Oct. 16, 1930, 32,000 kw. of power were transmitted from Columbus, Ohio, steam plant of Cincinnati system to Louisville over new 82-mi., 138,000-volt transmission line; principal features of interconnection; map showing course of line is given.

LIGHTNING PROTECTION. Slow Cloud Ionization Confirms Direct-Stroke Theory, C. L. Fortescue. *Elec. World*, vol. 98, no. 10, Sept. 5, 1931, pp. 420-421. Field experiences have given firm support to theory that direct stroke rather than induced stroke is cause of transmission outrages due to lightning; discharge time precludes induced voltage; one of primary requisites of ground wire protection therefore is that ground wire shall always interpose itself as shield against oncoming strokes. Before Am. Inst. Elec. Engrs.

VIBRATIONS. Dampers Installed on "Hot" 110-Kv. Line, P. J. Ost. *Elec. West*, vol. 67, no. 3, Sept. 1, 1931, pp. 114-115, 1 fig. Electrical department of City of San Francisco will install some 10,600 vibration dampers on its Hetch Hetchy transmission line; this line is of double-circuit, steel-tower construction carrying two 110-kv. circuits of 397,500 cir. mil A.S.C.R. conductors suspended from ten-unit insulators; equipment is described.

Vacuum Tubes

The Variation of the Resistances and Interelectrode Capacities of Thermionic Valves with Frequency, L. Hartshorn. *Experimental Wireless*, vol. 8, no. 95, Aug. 1931, pp. 413-421, 5 figs. Nature of changes and their order of magnitude are considered and estimation of errors arising from usual assumptions will be possible in any given case.

DETECTOR. A Method of Calculating the Performance of Vacuum-Tube Circuits Used for the Plate Detection of Radio Signals, J. P. Woods. *Univer. Texas—Bul.*, no. 3114, Apr. 8, 1931, 71 pp., 21 figs. Complete mathematical analysis pertaining to standard signal; detection of small signals; ideal detection; limited theory of large signal detection; extension to include pure resistance loading in grid and plate circuits; power series analysis of static characteristic; analysis of detection performance of UX-201A vacuum tube. Bibliography.

HOT CATHODE. A Method of Determining the Impedance of Hot Cathode Discharge Tubes, W. F. Westendorp. *Rev. Sci. Instruments*, vol. 2, no. 8, Aug. 1931, pp. 437-446, 8 figs. By means of superposed alternating current negative resistance of hot cathode neon and mercury direct current arcs was measured and found to follow closely slope of static characteristic of neon arc and to be widely different in case of mercury arc; at same time reactance for ripple current in arc was determined.

THYRATRON. Some Characteristics of Thyratrons, J. C. Warner. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 9, Sept. 1931, pp. 1561-1568, 6 figs. Fundamental characteristics; comparison with characteristics of high-vacuum tubes to show outstanding advantages and limitations; starting characteristics; typical examples; several types of thyratrons described.

Watthour Meters

INDUCTION. The Induction Watt Hour Meter, J. L. Ferns. *Elec. Times*, vol. 80, no. 2078, Aug. 20, 1931, pp. 275-277, 5 figs. Methods of producing phase difference for friction compensation; prevention of creep; quadrature adjustment; driving torque; brake torque; temperature variations; voltage variations; frequency variations; wave form variations.

Welding

LOCOMOTIVE FRAMES. Arc Welding of Locomotive Frames—I and II, J. M. Vossler. *Welding*, vol. 2, no. 8, Aug. 1931, pp. 511-513, 7 figs. Method of filling in vees, proper selection of electrodes and relieving of strains by heat treatment are important factors in securing sound weld.

PIPE. Welding Brass and Copper Piping, D. W. Endicott. *Am. Welding Soc.—Jl.*, vol. 10, no. 7, July 1931, pp. 26-29, 6 figs. Advantages of welding construction; investigation by Linde Air Products Co., to determine most desirable type of design for joints in copper and brass tubing, best welding procedure, most suitable welding rod, weldability of joints in various positions, and relative strength of various joint designs.

JOINTS. Pipe Welding—How, When and Where to do it—III, W. Spraragen. *Welding*, vol. 2, no. 7, July 1931, pp. 450-454, 7 figs. Application of welding; fabrication of large 82-in. receiver pipe for Westinghouse cross-compound steam turbine; comparative cost of header construction; graphic representation of stress transfer in collar and vee-type joints; manufacture of pipe by automatic carbon arc process.

STEEL STRUCTURES. Structural Arc Welding Progress, A. F. Davis. *Welding Engr.*, vol. 16, no. 8, Aug. 1931, pp. 42-46, 10 figs. Paper before West. Metal Congress, previously indexed from Metal Progress, Feb. 1931.

STRUCTURAL STEEL. Welding of Structural Steel, J. Ferguson. *Am. Welding Soc.—Jl.*, vol. 10, no. 7, July 1931, pp. 39-43, 12 figs. Enumeration of 10 advantages of welding; means of which welding may be advanced; factors affecting proper fabrication of welded steel. Before Am. Welding Soc.

Welds

ANALYSIS. Dissolved Nitrogen Embrittles Weld Metal, F. R. Hensel and E. I. Larsen. *Metal Progress*, vol. 20, no. 3, Sept. 1931, pp. 44-47, 5 figs. Investigation of effect of nitrogen on properties of welds at Westinghouse Research Laboratories; analyses of welded pads; to improve arc welds materially nitrogen must be reduced below 0.05 per cent; micros showing dispersion hardening of iron nitride.

STRENGTH. The Strength of Frontal and Lateral Welds, E. Hoehn. *Engineering*, vol. 132, no. 3419, July 24, 1931, pp. 115-118, 22 figs. Lap welds may be frontal or lateral; term lateral denotes weld which runs parallel to line of action of resultant load on weld, while in frontal weld fillet stands square to resultant force; test results show that specific resistance diminishes as height of fillet increases; causes of decrease in resistance of frontal welds to tearing are explained, and empirical rule found for its variation with height of fillet. Translated from report to Swiss Boiler Owners' Assn.

Industrial Notes

220,000 Volt Transmission Line Across the Susquehanna.—The work of carrying the transmission line from the Safe Harbor hydroelectric development across the Susquehanna River is now being completed. The crossing, which is over two railroads and a mile stretch of river, is between hills some 300 feet high. There are two spans of 3,000 feet each between a tower on an island near the middle of the river and those on the high hills on either side. In all, ten cables of aluminum-steel are to cross the river. The cables will carry power over a 70 mile, 220,000 volt transmission line to the system of the Consolidated Gas, Electric Light and Power Company of Baltimore. Safe Harbor will also be interconnected with the power development of the Pennsylvania Water & Power Company at Holtwood on the Susquehanna River.

Insulators for Pennsylvania Electrification.—A large order for porcelain insulators has been placed by the Pennsylvania Railroad with the Westinghouse Electric & Manufacturing Company. These insulators will be used in the new electrification now being continued toward Washington from Wilmington. If shipped at one time this order would make a freight train of 82 cars of 30,000 pounds capacity each. According to the Westinghouse Company, the transmission system for which these insulators are ordered exceeds in magnitude any previous undertaking for railroad operation in the world and uses 132,000 volts to carry the current to the various substations.

Power-Factor Correction Condensers for P. & L. E. R. R.—An order from the Pittsburgh & Lake Erie Railroad Co., for 45 units each of 4½ kva., 2,300-volt rating, has been received by the Dubilier Condenser Corporation, New York. The units are the standard Dubilier 5 kva. units, weighing 73½ pounds, and measuring 5 by 17 by 21 inches. They are to be installed at Colona, Pa., for power-factor improvement.

New High Voltage Rectifier.—What is claimed to be the largest continuous rating of dry, metallic rectifier for a given space is included in a new line of high voltage rectifiers announced by the B-L Electric Manufacturing Company, of St. Louis. Occupying a space of only 7¼ x 2¾ x 2¼ inches, this rectifier may be given a continuous output rating of 75 watts. It will operate directly from a 115 volt a-c. line.

Will Introduce New Fuse.—Dana Harland will direct the sales of the new "AE" fuse that is being introduced to the electrical industry by the Associated Engineers Company, of Chicago. The "AE" fuse is one of a long list of electrical improvements developed by the Associated Engineers Company, of Chicago, since its organization in 1908.

New Building for Jefferson Electric Company.—Announcement has been made that a contract for the construction of a new $550,000 plant has been awarded by the Jefferson Electric Company, of Chicago, to The Austin Company, engineers and builders, of Cleveland. The site is at the southwest corner of 25th Avenue and Madison Street, in Bellwood, and comprises approximately 19 acres of property. When the plant is completed on January 15, 1932, the company will abandon its present manufacturing units at 15th and Laflin Streets and Congress and Green Streets, Chicago. The Jefferson Electric Company was formed twenty years ago and merged five years ago with the Chicago Fuse Manufacturing Company.

New Time Switch.—A new Sauter, synchronous motor time switch is announced by R. W. Cramer & Company, Inc., 67 Irving Place, New York, the outstanding feature of which is a self-starting, slow speed synchronous motor. It is designed to operate at a certain speed in exact time with the frequency from the generating station, so that any number of these switches may be used to control multiple street lighting, sign and store window lighting, off-peak water heating and other time controlled circuits, all being turned on or off at the same time. It is equipped with laminated brush type copper contacts with silver arcing tips—quick make and quick break, and can be furnished in 2, 10, 15 and 25 ampere capacities for 110/220 volts, the synchronous motor being for use on 110 volts, 60 cycles.

Trade Literature

Contact Points.—Booklet, 24 pp., "Metallurgy and Design of Contact Points." Includes tables and diagrams illustrating the standard forms of contact points and fixtures available. Fansteel Products Company, Inc., North Chicago, Ill.

Insulated Cable.—Bulletin GEA 1312, 104 pp. Presents a compilation of information on all types of rubber insulated and miscellaneous insulated cable, including data on the selection of cable. General Electric Company, Schenectady, N. Y.

Fuses.—Booklet, 18 pp. The booklet gives a history of the invention and development of the fuse. It describes fuse construction and operation, as well as maintenance, and correct selection. Tables are included giving the sizes necessary for protection of motors and other appliances. Bussmann Manufacturing Company, University at Jefferson, St. Louis, Mo.

Wood Pole Specifications.—Bulletins. Contain the new American standard pole specifications for western red cedar, northern white cedar, creosoted yellow pine, and chestnut. In each case the specifications are tentative, but the dimensions are standard, and both were approved June, 1931. Inquiries should indicate which of the four specifications are of particular interest. Naugle Pole & Tie Company, 5 So. Wabash Avenue, Chicago, Illinois.

Thrust Bearings.—Bulletin HV, 40 pp. Describes vertical and horizontal thrust bearings whose parts are to a large extent interchangeable. Only standard, self-aligning, equalizing thrust bearings are covered therein. Capacities, weights and principal dimensions are given for the usual forms of these bearings. Kingsbury Machine Works, Inc., Frankford, Philadelphia, Pa.

Distortion Factor Meter.—Bulletin F-311, 4 pp. Describes type 536-A distortion factor meter for use in determining harmonic content of broadcasting station output, and to check through the amplifier in order to determine the source of distortion. The distortion factor is read directly on the dial, and the only operations required are those of throwing the switch and adjusting a potentiometer. General Radio Company, 30 State Street, Cambridge A, Mass.

Short-Center Drives.—Catalog, 148 pp., is described as an entirely new treatise of efficient short center drives compiled by the engineering staff of E. F. Houghton & Company. The book contains charts, tables and engineering data on 5,000 standard "Vim" efficiency drives ranging from 5 to 100 horsepower. A special mineral tanned leather belting is employed in these drives. The book was originally published for use by the company's field men, to assist them in discussing and working out transmission problems with engineers, and therefore it is not for general distribution. Copies will be delivered directly by a distributor to executives and engineers, interested in transmission drives, who will send in their requests in writing. E. F. Houghton & Company, Philadelphia, Pa.

DO YOU wish your twelve 1931 copies of Electrical Engineering bound for permanent record purposes? (*See p. 18 advertising section.*)

ANNUAL index to Electrical Engineering for 1931 is being published in separate pamphlet form; a copy is available without charge to each member or subscriber if requested before January 15, 1932. (See announcement, *p. 22 advertising section;* order form, *p. 992.*)

DR. M. I. PUPIN, one of the Institute's nine living Honorary Members, introduces an exact theory of inductive balancing networks for submarine telegraph cables. (*See p. 933-6.*)

A NEW scheme is proposed for reading watthour meters over telephone lines. (*See p. 942-4.*)

RESEARCH in dielectrics has witnessed an unusual intensity during the past year in the study of insulating liquids. (*See p. 967-70.*)

UNUSUALLY active participation by Enrolled Students was but one of the noteworthy features of the recent Kansas City district meeting reported in full in this issue. (*See p. 973-5.*)

THAT engineers will "share generously" is evidenced by the plans already under way for participation by the Institute's Sections in the organization of local engineers' unemployment relief committees. (*See p. 975.*)

FOURTEEN technical sessions, interesting inspection trips, and special entertainment features, represent the principal attractions of the forthcoming winter convention, plans for which rapidly are assuming final form. (*See p. 971-2.*)

PROCESSES involved in the extinguishing of the short a-c. arc, as encountered in circuit interrupters and in low voltage power distribution networks, have been subjected to rather close scrutiny in a group of three articles. (*See p. 948-57.*)

IN THIS month's article of the Engineering Foundation series "Has Man Benefited by Engineering Progress?" it is stated that "the growth of understanding by the many will form the foundation for a new and greater progress." (*See p. 947.*)

UNFORTUNATE rotor and stator slot combinations in induction motors often cause serious irregularities in their operating characteristics. Some of the many angles of this perplexing situation are reviewed in a group of three articles. (*See p. 936-42.*)

THOSE concerned with the operation of electric power cables are referred to (1) a simple method of calculating cable temperatures under variable loads (*see p. 944-6*) and (2) methods for calculating sheath losses due to the proximity of electric power currents (*see p. 965-6*).

Nerve Injuries From Electric Shock

During the last few years the authors have been studying the effect of electricity upon the nervous systems of experimental animals. In this article are discussed briefly the types of changes found in the brain, the spinal cord, and in the nerve cells themselves following an electric shock.

By

University, Baltimore

LABORATORY experiments made at The Johns Hopkins University to determine the effect of electric shock upon living animal organisms now have reached a considerable total, and well may be divided into groups according to the specific question being studied upon the occasion of the various groups of tests. This classification is indicated in the accompanying bibliography to which the numbered references apply. The scope of the article[6] which appeared in the June 1931 issue of ELECTRICAL ENGINEERING was limited to a comparison of the final results as they affected the physical well-being of the subject of the experiment, the article in effect being supplementary to one previously published.[1] It is the aim of the present article to describe and discuss briefly the results observed by microscopic study of the central nervous system in specimens subjected to shock according to experiments previously reported. The actual changes following an electric shock as found in the brain, spinal cord, and the nerve cells themselves are outlined.

Because of their convenient size and because a rat's heart is not easily damaged by electric current these animals were used as the experimental subjects in all cases, thus making it possible to focus the attention upon the nervous system. In each case the rat was given ether before the shock was applied. Directly after death the brains and spinal cord of each rat were removed and immediately "fixed" in suitable solutions to avoid postmortem changes. This material was sliced and examined, first with the unaided eye, and later microscopically to permit a detailed study of the nerve cells. However, only a part of the material subjected to this microscopic study was derived from the experimental subjects; the nervous systems of two electrocuted men also were examined.[5]

In the first series[1,2] a number of animals were studied after being subjected to a-c. or d-c. shocks of 110, 220, 500, or 1,000 volts. The time of contact varied in each group. In that series the electrodes were applied to the top of the skull and the base of the tail. For the 110- and 220-volt circuits more serious injuries resulted from a-c. than from d-c. shock, while with a circuit potential of 500 volts, the effects of a-c. and d-c. shock were approximately equal. For circuit potentials of 1,000 volts it was clear that the d-c. shock produced a greater injury than the a-c. shock, particularly when the time of application was taken into consideration.

For the different potentials of both alternating and continuous current, rather definite characteristic abnormalities[3,4] were found in each group shocked. The d-c. shocks more often produced symptoms of irritation to the nervous system, such as convulsions, whereas many of the rats receiving a-c. shocks showed paralysis of the posterior portion of the body directly after the shock. These paralyzed animals were quiet, would not eat, and never lived longer than two or three days. These latter cases when studied after death showed an abnormally soft spinal cord; and microscopic observation of cross-sections of the cords revealed that an area of hemorrhage, extending over a relatively long portion of the cord, had severed nervous pathways. In all cases the great majority of hemorrhages in the spinal cord occurred in the areas indicated in Fig. 1, although of course some were found in other places. Similar hemorrhages but usually smaller, occurred in the region of the brain. When these existed in the region controlling respiration, they were considered responsible for the death of the animal. In some cases hemorrhages were present also in the tissues covering the brain.

In the cases of experimental animals it may be said of hemorrhages that: (1) in the nervous system they are responsible for the immediate or subsequent death of a certain group subjected to contacts with electric circuits; (2) they are much more common after contact with a-c. circuits than after contact with d-c. circuits; and (3) they increase in number with the increase of circuit potential. Hemorrhages have been found also in the brains of men who have died as the result of similar shocks. Such hemorrhages probably are caused

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

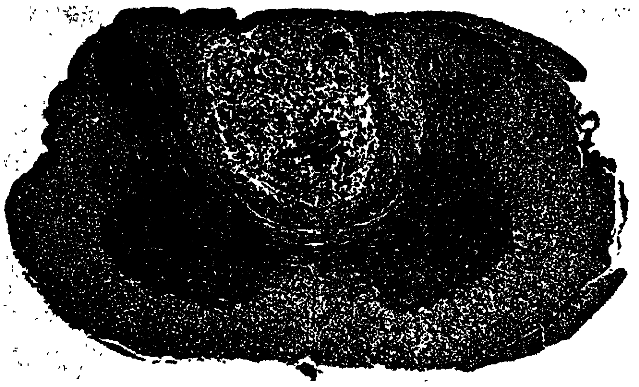

Fig. 1. Cross-section of the spinal cord of a rat

The hemorrhage which may be noted in the upper and central portions is typical of the effect which caused paralysis of the hind legs and subsequent death of the animals

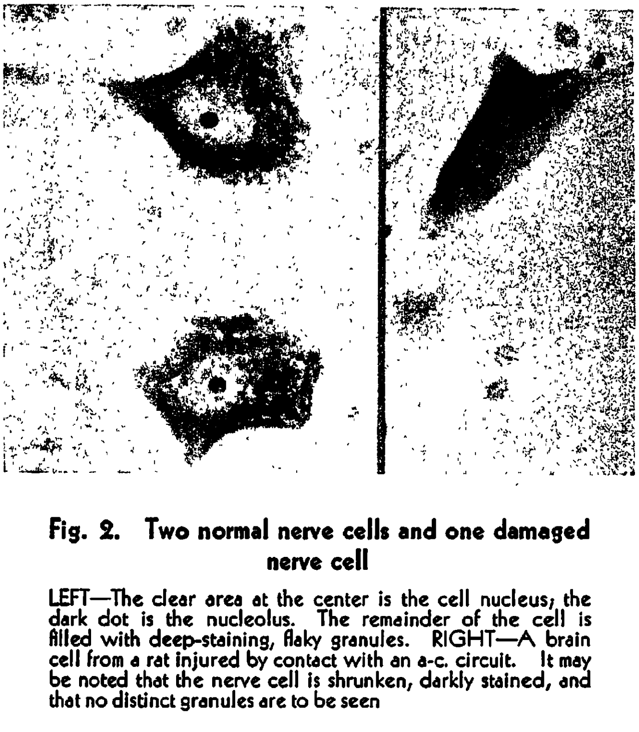

Fig. 2. Two normal nerve cells and one damaged nerve cell

LEFT—The clear area at the center is the cell nucleus; the dark dot is the nucleolus. The remainder of the cell is filled with deep-staining, flaky granules. RIGHT—A brain cell from a rat injured by contact with an a-c. circuit. It may be noted that the nerve cell is shrunken, darkly stained, and that no distinct granules are to be seen

by the sharp rise of blood pressure which follows the breaking of the contact with an electric circuit.

During the period of current flow, the blood collects in the veins, being squeezed from the heart and arteries by the contraction of the muscles in their walls. When the heart resumes its beating all this blood is forced back at once into the heart and arteries often overtaxing the capacity of the arteries and resulting in ruptures in their walls. With either a-c. or d-c. 1,000-volt circuits, severe burns often occurred around the electrode, in some cases resulting in an erosion of the skull beneath the head electrode and even burning the surface of the brain itself. (This would be a rare type of injury in man inasmuch as the head seldom lies in the direct pathway of the current.) Generally the burns from contact with a 1,000-volt d-c. circuit wree found to be more severe than those from a 1,000-volt a-c. circuit.

In this group of rats where the current passed through the head, changes in the nerve cells could be demonstrated even when animals died at once following the shock. After shocks at 500 and 1,000 volts these changes were more marked than after the lower voltage, as might be expected. In addition, they were more severe as a result of d-c. shocks than with a-c. shocks. Nerve cell damage is illustrated in several of the accompanying photomicrographic reproductions.

In making these photomicrographic studies, the finer cell structures are differentiated by staining the cells with a basic aniline dye. Certain portions of the cell have an affinity for basic dyes; others for acid dyes. In Fig. 2 the left-hand illustration shows normal nerve cells stained with an aniline dye demonstrating the characteristic granular structure of the cell. The cell edges are not regular, but are prolonged outward into angles which form the origin of nerve fibers. The clear area which always lies in the center of normal cells represents the nucleus, and near its center contains a black dot which is known as the nucleolus. Around the nucleus there are fluffy deep-staining granules which fill the remainder of the cell, always arranged in this characteristic manner with the type of cells represented in the illustrations. The granules probably are formed after death by the coagulation of some protein substance. Nerve cells injured by the passage of an electric current through the body, some from the brains of rats and others from human material, are reproduced in Figs. 2, 3 and 4.

Experience shows that all nerve cells even in a given group do not show an equal amount of damage as the result of an electric shock, several normal cells often being found among others that have suffered great changes. Extensive microscopic studies support the belief that cells having the potentialities of recovery may be differentiated from those rendered completely and permanently functionless. In this connection the nucleus is the real index of the ultimate fate of the cell; if it shows marked damage the cell will die. In the cases of experimental animals that recovered from the immediate effects of shock and were killed three or four days later, the nerve cell changes could be demonstrated with even greater clarity than in those animals which did not survive the shock. There appeared to be many cells which were permanently damaged, and others having the potentialities of recovery.

When a man suffers an electric shock which stops his breathing, artificial respiration should be continued for a prolonged period in order to give the nerve cells controlling respiration time to recover their normal functioning. Of course in the cases where changes in the nerve cells are extremely severe, recovery naturally cannot be expected, but since this cannot be predetermined the only safe and logical course is long-continued resuscitative effort.

Another question which arose had to do with the probability of injury to nerve cells when those cells did not lie in the direct path of the current. To test this question [6,7] the electrodes were shifted from one portion of the body of the experimental subject to another, and either a-c. or d-c. shocks at 1,000 volts were applied for one second. These resultant experimental findings demonstrated clearly that such contact caused damage to nerve cells only in that portion of the nervous system traversed by the current. Of course a current traversing the chest may produce serious changes in nerves controlling breathing and this injury of the nerve fibers is reflected in the cells from which they arise. It has been shown that electricity may produce a temporary block to nerve fibers as well as in nerve cells.

It is of importance to note that the type of changes produced in nerve cells by electric shocks are nonspecific and may be caused by other physical and toxic agents. Very high bodily temperature may damage nerve cells, and it is an established fact that body temperature rises rapidly in the case of electric shock if the circuit is closed for any length of time. This is supported by the results of autopsy performed on a man who suffered accidental death by contact with a 2.2-kv. 60-cycle circuit. The contact was from one arm to one leg, lasted several minutes, and badly burned the body. In this case the brain cells showed marked changes, even though that region did not lie in the direct pathway of the current. Therefore it must be considered, that if the body temperature is elevated to a considerable degree, changes everywhere in the delicate nerve cells must be expected. These changes are indistinguishable from those produced by electricity alone.

To eliminate heat as a source of nerve cell damage, several experiments were conducted using a small impulse generator[8] as the source of the electric shock. Circuit constants were so chosen that the entire duration of the surge did not exceed 4.5 microseconds, while the maximum current was about 100 amperes and the potential, 200 kv. The small amount of energy involved, coupled with the extremely short duration of the surge, produced little or no temperature rise in the animals subjected to the test. These rats were oriented in different ways with respect to the electric discharge so as to obtain results from current passage through different portions of the body. Marked changes in the nerve cells themselves were found in the brain and spinal cord of the subjects when it was traversed directly by the surge current. It is clear therefore that an electric discharge produces profound changes in nerve cells, even in cases where heating is not a possible factor. When the period of contact is prolonged, heat undoubtedly produces marked alterations.

In addition to heat there is another cause which affects nerve cells lying outside the current path. Where, for example, the contacts are at points on the same arm or leg, the passage of the electric current between these points gives rise to violent impulses which the peripheral nerves transmit to the brain. When these impulses are very strong they may produce a condition of shock akin to that perceptible after operations and fractures. This, the authors believe, is the explanation of death which occurred in several of the rats, following the passage of an electric current from hind leg to hind leg.

Injury to the nervous system resulting from electric shock has been studied recently by Morrison, Weeks, and Cobb[9] working independent of the present

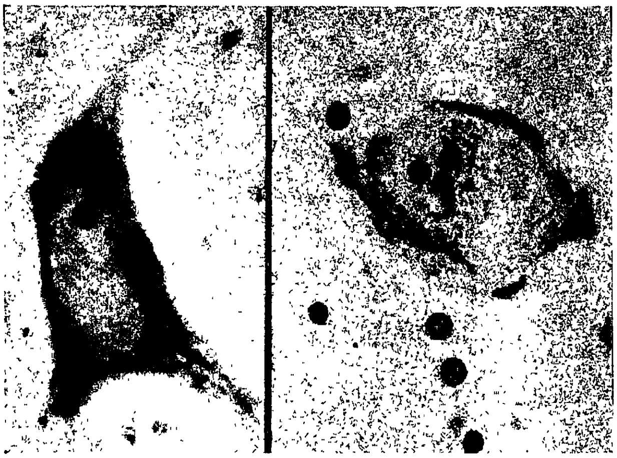

Fig. 3. Two damaged human nerve cells

RIGHT—From the brain of a man killed by a prolonged contact with a 2.2-kv. a-c. circuit. The edge of the nucleus may be noted to be irregular and to stain darker than normal; its nucleolus is swollen. There are few granules remaining in the cell. LEFT—From the brain of a legally executed twenty-four year old man. It may be noted that the nucleus edges are indistinct, the nucleolus swollen, and that there has been a loss of granules from the center of the cell

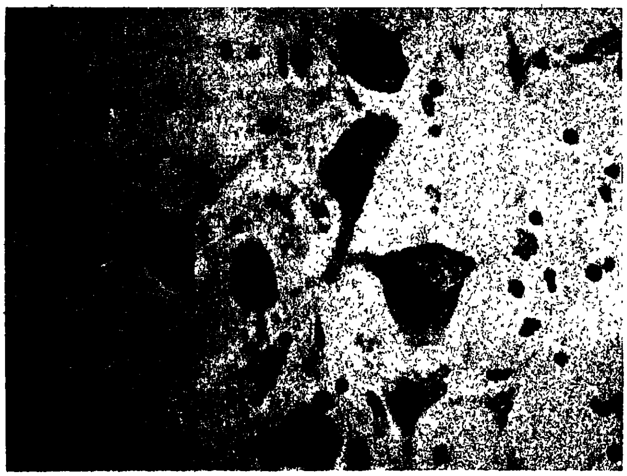

Fig. 4. Damaged human nerve cells

A group of cells from the nerve center controlling breathing, from the brain of a man killed by contact with a 2.2-kv. circuit. It may be noted that the nucleus is pushed to one side of the cell and that there are but few granules authors. Their findings agree well with those reported in this article.

The authors wish to take this opportunity to acknowledge the support given to this work by the committee on physiology of the conference on electric shocks.

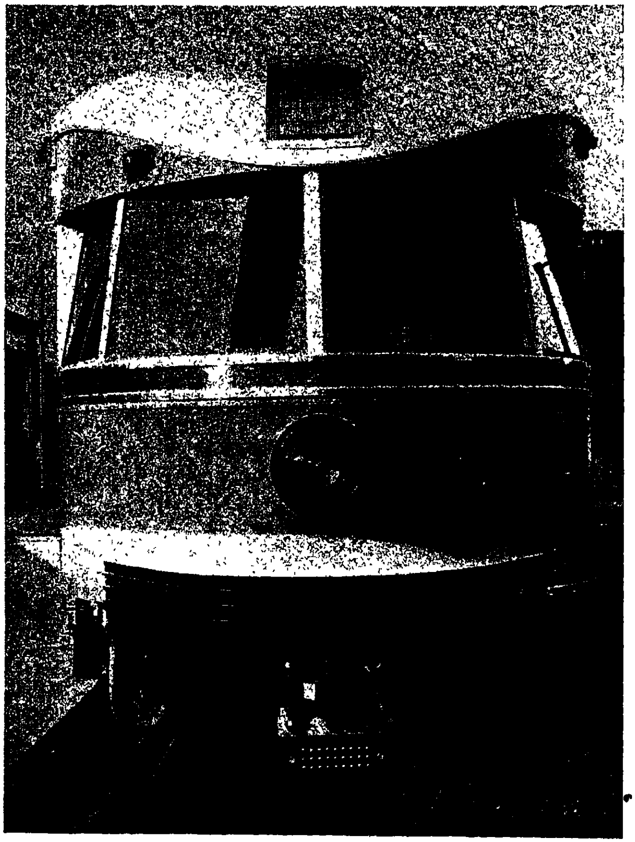
New Interurban Cars Secure High Speed at Low Cost

TEN STREAM-LINE aluminum-body cars capable of a speed of 80 miles per hr. are being placed in service by the Philadelphia and Western Railway Company for suburban traffic. The running time of express cars from Norristown to the 69th Street station in Philadelphia, a distance of 13½ miles, is scheduled to be cut from 24 to 16 min. by these new 52-passenger cars which weigh but 25 tons and are equipped with four 100-hp. motors operating under automatic control. The cars are being constructed by the J. G. Brill Company and the electric equipment is being supplied by the General Electric Company.

Under the direction of Prof. F. W. Pawlowski, professor of aerodynamics at the University of Michigan, exhaustive wind tunnel experiments have been conducted to assist the designers in cutting air resistance to a minimum. The windows are flush with the side surfaces of the cars, the under-floor equipment is planned to reduce air resistance, the cars, on the underslung principle, have a low center of gravity, the roof is relatively low, and each end of the car has a sloping roof and pointed nose. The entire body is aluminum, with a polished aluminum "belt rail" and "skirt" running from end to end below the windows, adding greatly to appearances. Wind-tunnel tests showed that with the conventional cars operating between 70 and 80 miles per hr. more than 70 per cent of the total power is consumed in overcoming air resistance. The stream-line design of these new cars will save approximately 20 per cent of the power required to propel them at speeds above 60 miles per hr.

The weight per horsepower of the 600-volt motors has been reduced from the usual value of 30 or 35 lb. per hp. to 26.8 lb. per hp. This has been accomplished by the use of fabricated gear cases, cast-steel semi-fabricated frame heads, and modifications of motor frame design. Self-ventilation of the motors has been improved by the use of a fan mounted on the commutator end of the shaft. With the motor control system employed, starting currents are held automatically to the highest permissible values consistent with good commutation; thus every acceleration is the maximum which can be obtained successfully. This new type of high speed, light weight car providing fast and comfortable service is expected to result in increased patronage, higher schedule speed with lower platform costs, lower maintenance costs, and a saving in power consumption.



Front view of one of the new high-speed stream-line cars soon to be placed into service by the Philadelphia and Western Railway Company

Balancing Cables by Inductive Networks

Greater transmitting speeds are possible in submarine telegraph cables when balanced by inductive networks than could be obtained with the older resistance networks. In this article is presented the first exact theory of inductive balances of which two already are in successful practical operation.

By
M. I. PUPIN
Honorary Member A.I.E.E.

Columbia University
New York, N. Y.

ELECTRICAL BALANCING of submarine cables by a network of conductors for purposes of duplex telegraphy is an old art. As long as these cables had a fairly high resistance, as they did in earlier years, their signaling speed was necessarily low. Under these conditions a satisfactory balancing network, the well known artificial line, consisted of resistances connected in series, and capacitances connected from ground to each junction of two consecutive resistances. This network was the equivalent of a sectional conductor, each section having resistance and capacitance, but no inductance; electrical reactions of the network imitated the electrical reactions of the cable. At low signaling speed such a network gave satisfactory results when its sections were sufficiently small and when a sufficiently large number of sections was used.

In recent years long submarine telegraph cables of low resistance have been laid for the purpose of increasing the speed of signaling. The heavy cable laid eight years ago by the Commercial Cable Company between Canso, Nova Scotia, and the Azores has a resistance of only about one ohm per nautical mile; it was intended to transmit at the rate of 600 letters per minute. At this speed, however, the inductance reaction of the cable came into play and the old balancing network containing no inductance in its sections could not balance it. In duplex working this heavy cable had to be operated at a much lower speed to accommodate the non-inductive balancing network. The design of an efficient inductive network thus became a very important problem in the operations of this long low-resistance cable.

EARLIER INDUCTIVE NETWORKS

Even a superficial study of this problem made obvious the fact that the old balancing artificial line had to be changed by introducing in its sections suitable inductive elements in place of the simple resistances. It was obvious also that within a certain frequency interval the effective inductance and resistance of these elements must vary with frequency, simulating the variations of effective inductance and resistance of the corresponding sections of submarine telegraph cable which was to be balanced. This seemed to introduce into the problem an insurmountable difficulty.

Breisig (*Electrotechnische Zeitschrift,* November 1899) and, twenty years later, Pernot (*Journal Franklin Institute,* September 1920; *British Patent Specification,* 1922) discovered that the effective inductance and resistance of a submarine cable section vary with frequency somewhat like the effective inductance and resistance of the primary of a transformer with its secondary short circuited. This discovery led to several attempts to imitate in the balancing network the electrical reactions of a cable by inserting in the sections of the old artificial line, transformers with short-circuited secondaries or their equivalent, that is, inductance short circuited by a non-inductive resistance or by another inductance. The most noteworthy among these attempts were those of Murihead Company and Davis (*British Patent Specification* 216, 219, March 24, 1924) and of Gilbert (*U. S. Patent,* 1,533,178, April 1925). No results ever have been published

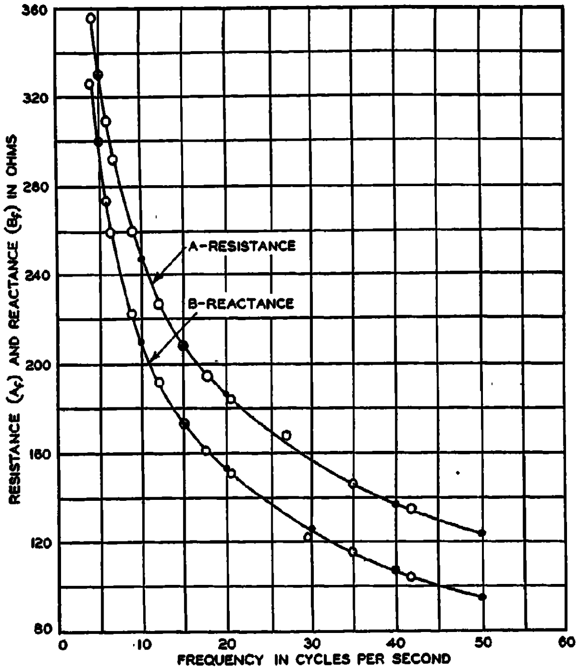


Fig. 1. Effective terminal resistance (A) and reactance (B) for a typical submarine telegraph cable (circles) and for the inductive network designed to balance it (dots)

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

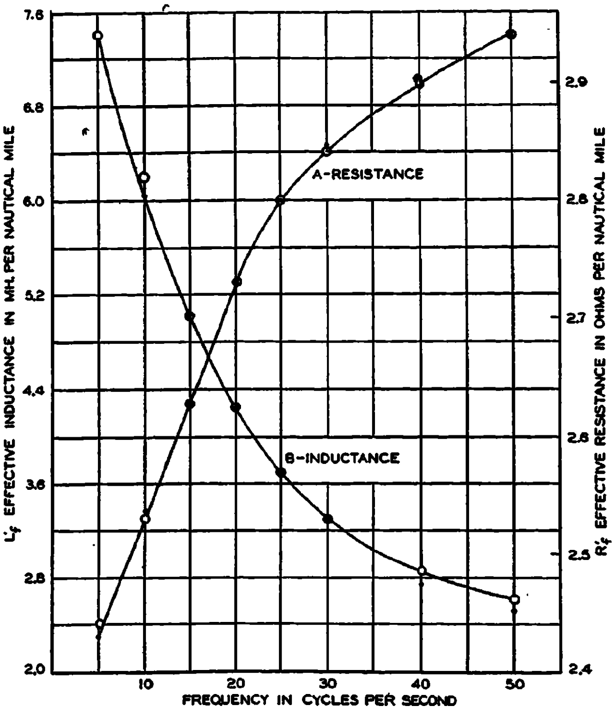

Fig. 2. Effective resistance (A) and inductance (B) per nautical mile for "equivalent" cable (circles) and for the network designed to balance it (dots)

which show how these applications of the old ideas of Breisig and Pernot succeeded in practise. It will be shown presently, however, that these applications cannot lead to a satisfactory balancing network since each section in such a network must be free from external electromagnetic disturbances. This means that the network inductances must have no stray fields in order to avoid mutual induction with the inductances in adjacent sections and with other external circuits.

Murihead Company and Davis, as well as Gilbert and others, not only overlooked this important provision, but, moreover, they *recommended* inductances with stray fields; the theory which they followed is not applicable to their structures since they invariably employed inductive elements having mutual induction not only with external circuits but also between sections of their networks. No mathematical theory of such networks exists, and just what are the determining factors in their design, is not clear.

Inductive Network With No External Field

In the following paragraphs will be discussed inductive networks having in their sections inductance coils with no external magnetic fields. In such networks the sections have no mutual induction with each other nor with external circuits; they are, therefore, free from external electromagnetic disturbances.

In a submarine cable which already is laid, the only quantities that can be measured are its terminal reactance and resistance at various frequencies. These measurements were made on a typical cable and formed the foundation of the study discussed here.

Curves A and B of Fig. 1 represent at various frequencies the effective terminal resistance a_f and the effective terminal reactance b_f of a cable as determined by wheatstone bridge measurements. The cable is one belonging to the Commercial Cable Company and connects Far Rockaway, Long Island, with Canso, Nova Scotia. Its constants are

Length.............. $l = 974.83$ nautical miles
Average capacity..... $c = 0.384$ μf. per nautical mile
Average copper resistance................ $r = 2.45$ ohms per nautical mile

Submarine cables are not of the same size at each point in their length; shore ends are much larger than deep sea parts, and hence the effective capacity and the effective inductance vary from point to point. The cable just referred to thus is not uniform, but a uniform cable which at all frequencies will have the same terminal reactance and resistance as this cable can be designated in theoretical studies; call it the *equivalent cable*. It can be specified as follows: Let C_f', R_f', and L_f' be the capacity, resistance, and inductance respectively per unit length of this equivalent cable at frequency f. Then if it is to have the same terminal reactances and resistances at various frequencies as those recorded in Fig. 1

$$a_f - i\,b_f = \sqrt{\frac{L_f'}{C_f'} - \frac{i\,R_f'}{p\,C_f'}}$$

or

$$(a_f^2 - b_f^2)\,C_f' = L_f'; \quad 2\,p\,a_f\,b_f\,C_f' = R_f' \qquad (1)$$

where $p = 2\,\pi\,f$

Make C_f' independent of the frequency and equal to 0.384 μ f., the same as the average capacity per unit length of the Far Rockaway-Canso cable. From eqs. 1 and curves A and B of Fig. 1, the effective resistances R_f' and inductances L_f' of the equivalent cable were calculated. From these calculations curves A and B of Fig. 2 were plotted for the frequency interval between 5 and 50 cycles per second.

An inductive network which can balance this equivalent cable obviously will balance also the original cable. Such a network will balance the equivalent cable at every frequency for which the effective inductance and resistance in its sections are the same as in the corresponding lengths of the cable. The aim of this study was to design a balancing network of this kind, employing in its sections inductance coils possessing no external fields. Several methods of construction were found to give very satisfactory results. The simplest of these is described here in some detail.

Network of Inductances in Series

The network discussed here employs in each of its sections two inductance coils connected in series as shown by coils 3 and 4 of Fig. 3. Each coil is toroidal in shape and thus has no external magnetic field; one is shunted by a simple resistance R_1. The unshunted coil has inductance l_0 and resistance r_0. Let L be the inductance of coil 4 and R its resistance, without the shunting resistance R_1. Then it can be shown that at frequency 10 s, and with coil 4 shunted by resistance R_1, the effective inductance L_{10s} and the effective resistance R_{10s} of the two coils connected in series will be

$$L_{10s} = \frac{L\,(1-a)^2}{1+s^2\,a_0^2} + l_0; \quad R_{10s} = \frac{(a+s^2\,a_0^2)R_1}{1+s^2\,a_0^2} + r_0 \tag{2}$$

Where $a = \dfrac{R}{R+R_1}$ and $a_0 = \dfrac{2\,\pi \times 10\,L}{R+R_1}$

At frequencies 10 s = 20 and 10 s = 30

$$L_{20} = \frac{L\,(1-a)^2}{1+4\,a_0^2} + l_0; \quad R_{20} = \frac{(a+4\,a_0^2)\,R_1}{1+4\,a_0^2} + r_0$$

$$L_{30} = \frac{L\,(1-a)^2}{1+9\,a_0^2} + l_0; \quad R_{30} = \frac{(a+9\,a_0^2)\,R_1}{1+9\,a_0^2} + r_0$$

Hence

$$\frac{L_{20}-L_{30}}{R_{30}-R_{20}} = \frac{L\,(1-a)}{R_1} = \frac{L}{R+R_1} = \frac{a_0}{2\,\pi \times 10} \tag{3}$$

As may be seen later eq. 3 has proved very useful in the theory of the design of inductive balancing networks.

If curves are plotted for L_{10s} and R_{10s}, the inductance and resistance curves given by eq. 3, then for the frequency interval from 10 s = 5 to 10 s = 50 the inductive network will balance the equivalent cable to the extent, only, that these curves coincide during that interval with curves A and B of Fig. 2. The problem of this study is, therefore, to adjust the physical constants of coils 3 and 4 (Fig. 3) so that within this frequency interval the curves for L_{10s} and R_{10s}, as given by eqs. 2 coincide as nearly as possible with curves A and B of Fig. 2. The frequency interval between 5 and 50 cycles per second is considered here because it is the important interval at the signaling speeds of the cable under consideration, that is, 600 letters per minute.

Assume that these curves coincide at frequencies 20 and 30, and that each section of the inductive network represents ten nautical miles of the equivalent cable; then

$$\left.\begin{array}{l} 10\,L_{20}' = L_{20};\ 10\,L_{30}' = L_{30} \\ \text{and} \\ 10\,R_{20}' = R_{20};\ 10\,R_{30}' = R_{30} \end{array}\right\} \tag{4}$$

Under what conditions will these coincidences occur? It will be shown presently that equation

$$\frac{L_{20}-L_{30}}{R_{30}-R_{20}} = \frac{L_{20}'-L_{30}'}{R_{30}'-R_{20}'} \tag{5}$$

determines these conditions completely, because (see eq. 3) it assigns definite values to all of the physical constants in eq. 2. These constants are: a_0, l_0, R_1, R, r_0, and $a = R/(R+R_1)$. The assumptions (eq. 4) leading to eq. 5 are, therefore, the foundation for the procedure of designing the inductive network considered here.

The right-hand member of eq. 5 has, according to Fig. 2, a definite numerical value equal to 1/109 approximately. The left-hand member of eq. 5 is equal to $a_0/(2\,\pi \times 10)$ according to eq. 3. Hence

$$a_0 = \frac{2\,\pi \times 10}{109} = 0.576$$

and

$$a_0^2 = 0.332$$

This constant a_0 in the equations of the inductance and resistance curves of the network is therefore fixed by experiment. The other constants in eqs. 2 also are definitely fixed by experiment as follows:

$$\frac{L_{20}-l_0}{L_{30}-l_0} = \frac{10\,L_{20}'-l_0}{10\,L_{30}'-l_0} = \frac{1+9\,a_0^2}{1+4\,a_0^2}$$

Whence l_0 = 18.30 mh.

Again from eq. 2

$$(1-a)^2\,L' = \frac{(10\,L_{20}'-l_0)\,(1+4\,a_0^2)}{L} = 56.57 \text{ mh.}$$

Having selected a convenient value for L, the inductance of the shunted coil without R_1, the constant $a = R/(R+R_1)$ also is fixed. It is 0.387 when L = 0.15 henrys. Since

$$1-a = \frac{R_1}{R+R_1} = \frac{R_1\,a_0}{2\,\pi \times 10\,L} = 0.613$$

$$R_1 = \frac{2\,\pi \times 10\,L \times 0.613}{a_0} = 10.0 \text{ ohms}$$

$$R = \frac{a\,R_1}{1-a} = 6.3 \text{ ohms}$$

$$r_0 = 10\,R_{20}' - \frac{(a+4\,a_0^2)\,R_1}{1+4\,a_0^2} = 20.0 \text{ ohms}$$

If therefore the physical constants of the two inductance coils in the sections of the inductive network have the values which have been calculated by means of eq. 5, then the inductance and resistance values will

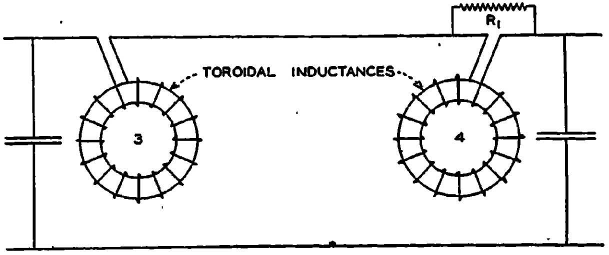

Fig. 3. Schematic diagram of a section of inductive balancing network with no external magnetic field

be as indicated in eqs. 4. The question now arises as to how the effective inductance and resistance curves of the two structures compare at other frequencies. This comparison is obtained easily by substituting successively different values of frequency from $10\,s = 5$ to $10\,s = 50$ in the following equations:

$$\left.\begin{aligned} L_{10s} &= \frac{56.57}{1 + 0.332\,s^2} + 18.3 \\ R_{10s} &= 20.0 + \frac{(0.386 + 0.332\,s^2)\,10}{1 + 0.332\,s^2} \end{aligned}\right\} \quad (6)$$

These equations are obtained by inserting in eqs. 2 the values of the constants just calculated.

The values of inductance and resistance thus calculated from eqs. 6 were plotted by dots in the curves of Fig. 2. The overlapping of the effective inductance and resistance curves of the equivalent cable with those of the inductive network certainly is remarkable. However, the overlapping of the terminal reactance and resistance curves is even closer as is indicated by curves *A* and *B* of Fig 1. In these curves the small circles denote values determined by wheatstone bridge measurements on the cable and referred to previously, while the dots denote values calculated by eqs. 1 from L_{10s} recorded on curves *A* and *B* of Fig. 2, and verified later experimentally by measurements on the inductive balancing network after this had been constructed.

Since the terminal impedance curves of the inductive network and of the equivalent cable coincide within the frequency interval between 5 and 50 cycles per second it follows that the network will balance the cable within that frequency interval. Practical operations are in complete agreement with this theoretical result. The same method of procedure was followed in the design and construction of inductive network balances of this type for other cable terminals, and in each case the result was just as satisfactory as in the case just described.

Irregularities in Speed-Torque Curves of Induction Motors

Recent investigations have thrown light on the hither to obscure causes of "cusps" in the speed-torque curves of polyphase induction motors, causing the motors to "crawl" at reduced speed or to be noisy and to vibrate under load. Results of some of these studies are described in the three articles following the introduction below.

SPEED-TORQUE curves of polyphase induction motors on test never have agreed with the smooth calculated characteristics. As a result of these unpredictable "hooks" or "cusps" in the speed-torque curve, some motors are found to crawl at unexpected speeds or are so noisy as to be useless for all practical purposes. Various explanations have been advanced as to the cause of these irregularities, but no satisfactory method of definitely predetermining the speed-torque curve could be found.

Certain factors, such as the harmonics in the revolving field caused by the distributed winding, or the relative number and shape of the stator and rotor slots, are known to influence the shape of the curve. However, dependence upon empirical rules for the selection of rotor slots always has been necessary. Rules such as the use of twice a prime number for rotor slots, or the avoidance of less than 20 per cent difference in stator and rotor slots, have passed from one designing generation to the next. A German engineer, Dr. W. Stiel, published other empirical rules devised from an extensive investigation of a large variety of slot combinations. As is to be expected, all these empirical rules not based on a knowledge of the disturbing phenomena often result in unpleasant surprises. Hence today manufacturers are led to the wasteful method of building a series of rotors with different slots whenever a new line of induction motors is required, to find by actual test which of the rotors is most satisfactory.

In the first two of the following three articles, attempts are made to determine the cause of the irregularities in the speed-torque curves, and to formulate rules for the prediction of these characteristics. The first article, by Kron, gives consideration to the slot combinations in the stator and rotor and indicates that the most powerful disturbing effects are due not to the distribution of windings in slots, but to the existence of the slot openings in the stator and rotor. As the result of a careful, mathematical analysis based on a new method of attack, involving the concept of "revolving permeances," definite rules are laid down by the author regarding the occurrence of vibration, noise, and crawling of induction motors. The second article, by Trickey, is concerned with the effect of harmonics in the rotating field, and the results, while not entirely in agreement with those in the first article, appear to be well substantiated by test. A possible explanation of the apparent discrepancy between these two investigations is that the first is concerned with rotors having a small number of slots so that the slots are relatively important, while the second deals more particularly with rotors having a large number of slots so that the slots become less important and the harmonics in the field have an increasing influence.

The third article of this group is a contribution from England, and gives the derivation of a formula for determining the short-circuit current obtained with skewed rotor slots in per cent of the short-circuit current obtained without skewed slots. By its use, the value of short-circuit current may be predicted for any angle of skew of the rotor slots. While this subject is somewhat controversial, it is of interest in connection with the other two articles, as skewing is resorted to in an effort to eliminate noise and crawling of induction motors at reduced speed.

Slot Combinations of Induction Motors

By
GABRIEL KRON
Associate A.I.E.E.

United Research Corp.,
Long Island City, N. Y.

AMONG the suggestions advanced as to the cause of irregularities in the shape of the speed-torque curves of polyphase induction motors which cause them to crawl at reduced speeds or to have excessive vibration and noise, is that the harmonic fluxes introduced by the distribution of the stator and rotor windings in slots may cause these irregularities. However, the conclusions of this analysis are not borne out by the facts, and the investigations on which this article is based show that the most powerful disturbing effects are due not to the distribution of the windings, but to the presence of the slot openings in the stator and rotor.

The existing methods of analyzing the influence of slot openings were found to be unsuitable for this particular problem, so another method of attack was devised, introducing the concept of "revolving permeances" to find what fluxes exist in an induction motor besides the fundamental flux when both stator and rotor are slotted, and what is the speed of these parasitic fluxes as the rotor rotates at any particular speed. With this conception and the general term of Fourier's series, the necessary rules and formulas may be expressed in simple forms.

REVOLVING PERMEANCES

It will be assumed that the slots are replaced by *effective* slots having rectangular shapes, as in Fig. 1(a), and that the lines of flux are parallel in the gap. To avoid the disturbing use of subharmonics and fractional harmonics, a flux with one pair of poles (two poles) will be called the first harmonic and a flux with p pairs of poles will be called the pth harmonic.

Let first both stator and rotor teeth be removed. The resulting gap has a constant permeance $\mathcal{P}_c$ and is represented in Fig. 1(b) by unit height.

Next, let the stator teeth be introduced. At those points around the circumference where stator teeth exist, the permeance increases. This change of permeance can be considered as if an additional stationary permeance, $\mathcal{P}_s$ consisting of rectangles, has been introduced. If the number of stator teeth is G_1, this permeance $\mathcal{P}_s$ can be expressed as a constant term plus a series of harmonic permeances $\Sigma A_k \cos k G_1 x$ where k is any integer. The largest of these is $A \cos G_1 x$, the harmonic permeance having G_1 pairs of poles.

Let now the stator teeth be removed and the revolving rotor teeth, G_2 in number, be introduced. This is equivalent to introducing an additional revolving permeance $\mathcal{P}_r = \Sigma B_k \cos (k G_2 x - v k G_2 \omega t)$ where v is the ratio of the rotor speed to the two pole synchronous speed S. (S is 3,600 with 60 cycles.) The speed of each of these permeances is $v k G_2/k G_2 = v$. The largest permeance is $B \cos (G_2 x - v G_2 \omega t)$, the one with G_2 pairs of poles.

If the stator teeth are *not* removed when the rotor teeth are introduced, at those points along the circumference where no stator teeth exist, the additional permeance is $\mathcal{P}_r$, same as above, but at those points where stator teeth do exist, the additional permeance is larger than $\mathcal{P}_r$ by the amount of an oscillating permeance $\mathcal{P}_o$. This permeance $\mathcal{P}_o$, due to the coexistence of slots, is much larger than $\mathcal{P}_s$ or $\mathcal{P}_r$. In decreasing the air-gap, $\mathcal{P}_s$ or $\mathcal{P}_r$ change very slightly, but $\mathcal{P}_o$ increases very rapidly.

As the rotor revolves, each part of $\mathcal{P}_o$ describes a peculiar cycle. The width of each rectangle increases from zero to a definite value, then moves along the

---

Based upon "Induction Motor Slot Combinations" (No. 31-46) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 26-30, 1931.

periphery, soon decreases and finally disappears. In spite of its complicated behavior it can be expressed easily in a Fourier's series by noting that if two series representing $\mathcal{P}_s$ and $\mathcal{P}_r$ are multiplied together the product represents the oscillating permeance $\mathcal{P}_o$. Hence

$$\mathcal{P}_o = \Sigma C_k \cos[(k_1 G_2 \pm k_2 G_2) x \pm v k_2 G_2 \omega t]$$

The largest among these revolving double-infinity harmonics is the one having $(G_1 - G_2)$ pairs of poles,

$$\mathcal{P}_o = C \cos[(G_1 - G_2) x + v G_2 \omega t]$$

revolving with a speed $[G_2/(G_1 - G_2)] v$. If G_2 is larger than G_1 this permeance revolves forward; if smaller, it revolves backward. With decreasing air-gap $\mathcal{P}_o$ increases rapidly and may reach a value of the same order of magnitude as the constant gap. It is this very permeance which causes most of the trouble.

Now, if p equals the number of pairs of poles of the stator winding, and an m.m.f. wave $M = M_r \cos(p x - \omega t)$ exists in the stator, it produces with each of the permeances two fluxes since flux = m. m. f. × permeance. Based on this theory rules can be formulated as to the behavior of induction motors with regard to crawling, vibration, and excessive noise. These rules, summarized below, have been substantiated by many tests and indicate that the assumption of rectangular rotor slots is justified.

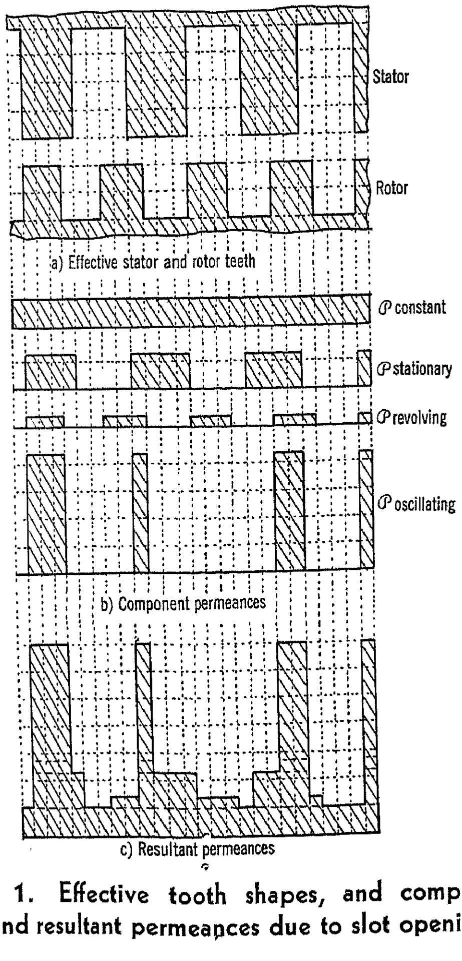

Fig. 1. Effective tooth shapes, and component and resultant permeances due to slot openings

SUMMARY OF RULES

A. Vibration and noise are liable to be present under the following conditions.

1. When the slots differ by one or by the number of poles plus or minus one, the fundamental m. m. f. and the oscillating permeance produce a flux differing by two poles from the fundamental flux. When the speed of the resulting unbalanced pull is the same as the critical speed of the rotor, circular vibrations and noise occur.

2. When the slots differ by half the number of poles, the fundamental m. m. f. and the oscillating permeance produce a fundamental single-phase flux. When the frequency of torsional vibrations is the same as the critical frequency of the rotor, torsional vibrations and noise occur.

3. When the slots differ by the number of poles the fundamental m. m. f. and the oscillating permeance produce a parasitic fundamental flux revolving with a different speed than the fundamental flux. These two fluxes set up torsional vibrations and noise, and also rumbling noises unaccompanied by critical vibrations.

The chances that the noise occurs in the working range are greater with smaller number of poles, higher speed and with smaller critical speeds. When these noises do occur, the motor is practically useless.

B. Crawling may be present under the following conditions.

1. When the slots differ by the number of poles and the rotor has more slots than the stator, the fundamental m. m. f. and the oscillating permeance produce a parasitic fundamental flux. At a rotor speed $S\,(2/G_2)$ the speed of the parasitic flux is the same as the speed of the fundamental flux, the two fluxes lock and the motor crawls as if it were a synchronous motor (reaction machine effect). When the rotor has less slots, the synchronous crawling occurs at a negative speed.

2. When the rotor slots are greater than $(G_1 + p)$ by, say 80 per cent, the fundamental m. m. f. and the stator slot-opening produce a flux having less poles than the number of rotor bars. At a rotor speed $S/(G_1 + p)$ the motor crawls due to induction motor effect.

3. When the rotor slots are greater than $(G_1 - p)$ by, say 80 per cent, crawling occurs at $S/(G_1 - p)$ if driven backward, due to the same reason as in 2.

4. When the rotor slots in a two-phase motor are divisible by the number of poles, the fifth harmonic flux due to the distribution of winding may cause crawling at one-fifth synchronous speed.

5. Any two-phase motor may crawl at one-third synchronous speed if driven backward, due to the backward revolving third harmonic flux caused by the distribution of windings.

6. When $G_2/2\,p$ is an integer equal to or close to unity, crawling may occur at S/G_2 due to the "Görges" effect.

7. When the vibrations under *A* occur at low speeds, the motor crawls.

8. When the harmonic flux, due to the distribution of winding, is large, say larger than 10 per cent of the fundamental, the motor may crawl.

C. Smaller irregularities and hooks in the speed-torque curve may appear under the following conditions.

1. When the rotor slots are greater than $(G_1 + p)$ a hook occurs at $S\,(G_1 + p)$ r. p. m.

2. When the rotor slots are greater than $(G_1 - p)$ a hook occurs at $S/(G_1 - p)$ r. p. m. if the motor is driven backward.

3. When the rotor slots are divisible by the number of poles, a hook occurs at S/G_2 r. p. m.

4. When the rotor slots are divisible by the number of poles, a hook occurs at one-seventh synchronous speed in a three-phase motor and at one-fifth synchronous speed in a two-phase motor. In both cases, the hook is accompanied by another hook at S/G_2 r. p. m.

5. When $G_2 = 2\,p\,(1 + k\,\psi)\,2\,p$, where ψ = number of phases, a small synchronous locking (synchronous motor) effect occurs at $S\,(2/k_2 G_2)$ r. p. m.

6. Any two-phase motor has a hook at one-third synchronous speed if it is driven backward.

7. When a winding introduces a harmonic flux larger than, say 8 per cent of the fundamental, it always produces a hook.

8. When the vibrations under A occur at higher speeds, proportionally smaller hooks occur at those speeds.

It should be emphasized that these rules are not necessarily complete. Those for smaller noises, which make the motor useless only for certain applications, are not considered at all in this article, neither are the variations of torque during starting and at very low speeds.

Field Harmonics in Induction Motors

By
P. H. TRICKEY
Associate A.I.E.E.

Westinghouse Elec. & Mfg. Co., East Springfield, Mass.

CUSPS in the speed-torque curves of induction motors have been attributed to several causes; first, to harmonics in the rotating field; second, to the synchronous locking-in of stator and rotor harmonics as shown by Dreese; and third, to the effect of the slot openings as shown by Kron. The present article is devoted exclusively to the study of the first cause, and indicates that harmonics in the field form do have a very definite effect on the speed-torque curve.

It may be assumed that each harmonic of the rotating m.m.f. causes a proportional rotating flux, and that each of these flux harmonics acts in the motor as if it were present alone. It then produces a small speed-torque curve whose torque is proportional to the fundamental torque, and whose speed is l/h times the speed of the fundamental for the same slip, where h is the order of the harmonic. On this basis,

$$T_h = h\,K_h^2\,C^2\,K^2\,T_1$$

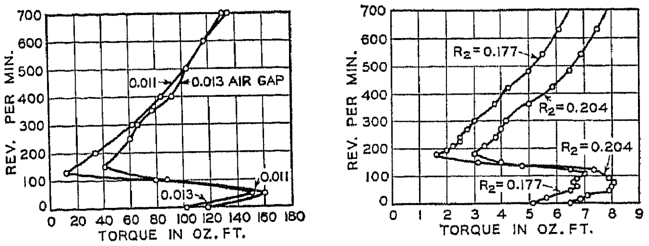
where

T_h = harmonic torque
K_h = magnitude of harmonic m.m.f. as a fraction of the fundamental
C = skew factor
K = distribution factor, dependent on the number of rotor bars
T_1 = fundamental torque at the same slip

As the harmonic torques do nothing but harm, they are eliminated or made as small as possible in normal design. K_h the magnitude of the harmonic m.m.f. is reduced by making the revolving field as nearly sinusoidal as possible. C may be reduced to zero for any one harmonic by skewing through twice the harmonic pole pitch. K is a function of the number of rotor bars, and is based on the fact that most induction motor theory is developed assuming an infinite number of bars. This brings a distribution factor of 0.637 into the formulas. With even as few as four bars per pole this factor changes little, but for the harmonic fields, the number of rotor bars per pole may be one or less. With one bar per pole K equals 2.46 and with one bar for two poles it becomes zero. However, since small numbers of rotor bars may bring in dangerous synchronous cusps, it is safer to use a large number of rotor bars, and when K begins to approach its maximum value, control by the skew factor.

There are three other means of reducing the cusps that are not apparent from the equation. First, the equation assumes that the flux wave is exactly the same as the m.m.f. wave. However, increasing the air gap will smooth out the harmonics, as indicated by Fig. 2. Second, the slot openings tend to increase certain of the harmonics, and therefore the openings should be made as small as possible. Third, while the magnitude of the harmonic torque is not reduced by increasing the rotor resistance, the fundamental torque is increased, and the resultant minimum torque is much greater. A typical case is shown in Fig. 3.

In order to study the effect of field harmonics, a special motor was built. A 48-slot primary was used to give sufficient slots per pole for the special windings, and to reduce the effect of slot openings, as the coil angle covered two or more slots. The rotor was chosen with 60 slots, a multiple of three to eliminate any possibility of the synchronous effect noted by Dreese, and of a greater number of slots than the stator to reduce "cogging" and to avoid possibility of the unlucky combinations that have occurred so many times with small numbers of rotor slots.



Figs. 2 and 3. Test curves of effect of increasing air gap (left) and secondary resistance (right)

Four separate windings were placed in the stator, all of different wave forms, and so located that their fundamental fluxes coincided exactly. The windings were all three-phase, four pole, 60 cycles, and designed for the same fundamental flux. The wave analysis of each winding is given in Table I, the meaning of the

---

Based upon "Cusps in the Speed-Torque Curves of Induction Motors" (No. 31-71) presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931.

positive and negative signs being indicated in Fig. 4. The four separate windings were arranged as follows:

Winding *A*	Two slots per phase per pole, full pitch
Winding *B*	Two slots per phase per pole, two-thirds pitch
Winding *C*	One slot per phase per pole, full pitch
Winding *D*	One slot per phase per pole, two-thirds pitch

This motor very clearly illustrates the effect of changing the wave form. Figs. 5, 6, 7 and 8 are the test curves of windings *A*, *B*, *C*, and *D* respectively. The speed-torque curves for windings *A* and *B* shown in Figs. 5 and 6 are nearly alike except for a difference

in reactance due to one winding being deeper in the slots. As may be noted, the generator torque of the 13th harmonic is great enough to cause the resultant torque to become negative and the motor operates at the low speed of the 13th harmonic and will not rise to full speed by itself. It will be noted in Fig. 7 for winding *C* that the 5th and 11th harmonics cause stable operation in opposite direction to the fundamental field.

It was also possible to secure other wave shapes by connecting the windings in different series combinations. Figs. 9, 10, and 11 further illustrate the effect of such recombination on the wave form. In these cases, certain of the harmonics cancel each other. Another method of illustrating the fact that the harmonic torques are present and are of considerable magnitude, is to place two windings in series with fundamental waves opposing and harmonic waves assisting. Fig. 12 shows the case of opposing windings *C* and *D*.

An attempt has been made in this article to bring out first, that the harmonics in the field form have a very definite effect on the speed-torque curves, and second, that the assumption of each harmonic acting separately, while not rigorously correct, is useful in determining the speed at which cusps are likely to occur.

Skewed Slots in Induction Motors

By
R. D. BALL
Associate A.I.E.E.
English Electric Co., Ltd.
Bradford, England

INDUCTION MOTOR slots are usually skewed to prevent "cogging" and noise on load, but indiscriminate skew irrespective of number of poles, especially when this number is large, leads to very large reduction of short circuit current and motor performance. The reduction of short circuit current is due not so much to increase of leakage reactance as to an unbalanced component of mutual flux.

In the following theory expressions are given for the ratio of short circuit current with skewed slots to short circuit current without skew, as a function of "dispersion coefficient" τ and skew angle.

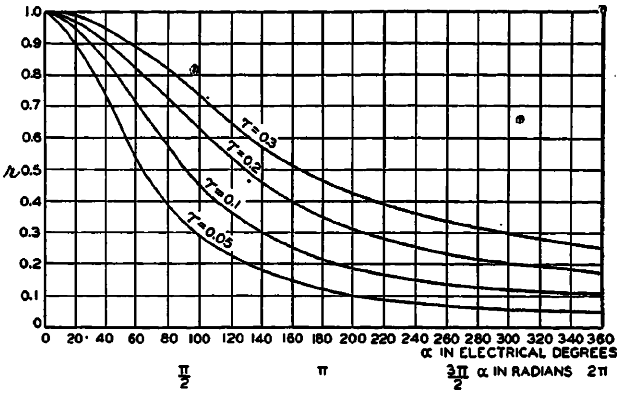

Fig. 13. Relation between short circuit currents, "dispersion coefficient" and skew angle

For the sake of simplicity, the motor is assumed to possess negligible primary and secondary resistance. The symbols used are as follows:

$\tau = \dfrac{X}{M} = \dfrac{\text{magnetizing current}}{\text{short circuit current without skew}}$ (approximately)

X = total leakage reactance

M = mutual reactance

f = skew factor = $\dfrac{2 \sin \dfrac{\alpha}{2}}{\alpha}$

α = skew angle = $\dfrac{\text{slot pitch skew}}{\text{total slots}}$ × pole pairs × 2π radians

V = applied voltage

I_1 = primary current

I_2 = secondary current referred to primary

$r = \dfrac{\text{short circuit current with skewed slots}}{\text{short circuit current without skewed slots}}$

If equal primary and secondary leakage reactance is assumed, we get the usual transformer equations

$$jI_1\left(1+\frac{\tau}{2}\right)M + jI_2Mf = V \tag{1}$$

$$jI_2\left(1+\frac{\tau}{2}\right)M + jI_1Mf = 0 \tag{2}$$

From eq. 2

$$I_2 = -\frac{I_1M}{M\left(1+\frac{\tau}{2}\right)}f = -\frac{I_1f}{\left(1+\frac{\tau}{2}\right)} \tag{3}$$

Substituting eq. 3 in eq. 1 we obtain

$$jI_1\left(1+\frac{\tau}{2}\right)M - jI_1\frac{M}{1+\frac{\tau}{2}}f^2 = V$$

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

$$I_1 = \frac{V}{jM\left[\left(1+\frac{\tau}{2}\right) - \frac{f^2}{1+\frac{\tau}{2}}\right]} \qquad (4)$$

Without skew, $\alpha = 0$, hence $f = 1$
Therefore

$$r = \frac{\dfrac{V}{jM\left[\left(1+\frac{\tau}{2}\right) - \frac{f^2}{1+\frac{\tau}{2}}\right]}}{\dfrac{V}{jM\left[\left(1+\frac{\tau}{2}\right) - \frac{1}{1+\frac{\tau}{2}}\right]}}$$

$$= \frac{\left(1+\frac{\tau}{2}\right)^2 - 1}{\left(1+\frac{\tau}{2}\right)^2 - f^2} \qquad (5)$$

From eq. 5 we can plot the ratio r as a function of τ and f. Curves are given in Fig. 13, which can be used as a guide when choosing the skew angle. It will be noticed that a small error, due to the various assumptions made for the sake of mathematical simplicity, is introduced for large values of τ at $\alpha = 360$ degrees, but skew of this order naturally is never met with in practise.

A Study of the Three-Circuit Transformer

THREE independent electrical circuits which are coupled together magnetically may be represented by an equivalent circuit developed from fundamental equations. In general, these transformers may be divided into two distinct types depending upon the relative directions of the mutual fluxes between the three windings. According to C. F. Estwick, (M'25) of the General Railway Signal Company, Rochester, N. Y., who discusses this type of transformer in a current A.I.E.E. paper, any arrangement of three coupled circuits will have the characteristics of either one or the other of the two types mentioned.

In the first type of transformer discussed by the author the coils in each circuit, or the cores on which they are mounted, are parallel to each other or arranged in the form of a Y. Under such conditions it is practically impossible to have a mutual flux threading through all three coils. In the second type the three coils are wound on one core or otherwise arranged on separate cores placed so that a path is provided for magnetic flux to interlink with the conductors in all three circuits. The author sets up equivalent circuits for both types of transformers, and for these derives equations which take into consideration the various mutual fluxes. To demonstrate the applicability of the formulas derived one simple typical problem is presented for each type of transformer.

Abstracted from "The Three-Circuit Transformer" by C. F. Estwick, (No. 31-69) presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931.

Remote Reading of Watthour Meters

A scheme is described whereby watthour meter readings may be "observed" over regular subscribers' telephone circuits.

By
A. S. FITZGERALD
Member A.I.E.E.
Wynnewood
Pennsylvania

REMOTE READING of electric meters in residences is not feasible by any of the several telemetering schemes so far developed on account of the amount and nature of special apparatus required at the meters being read. A scheme worked out in the General Electric Laboratory is described here in which the bulk of the apparatus is concentrated at the power company's premises, a simple electromechanical device being the only apparatus installed at the meter itself.

In this proposal, connection between the power company's "observing" apparatus and the consumer's meter is made by means of telephone lines, the connection being made through the power company's connection with the telephone central exchange, thence to the consumer's residence over the telephone company's regular subscriber's circuit. A special mutual agreement would have to be reached, of course, to permit the necessary interconnection of power and communication equipment. Any system of remote

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

A beat-frequency audio generator with four tuning dials corresponding to the four dials of the watthour meter is installed at the power company's office (left). Attached to the meter (right) is a simple electromechanical vibrating device fitted with four rows of ten reeds each, one for each digit. This unit is actuated by an electromagnet which in turn is energized by the audio generator via the telephone line. Each reed resonates at a different frequency but all within the frequency range of the generator. To obtain a reading the observer signals the telephone central-office operator and gives her the number of the party whose meter is to be read. After the connection has been established (without ringing or otherwise disturbing the consumer) the observer switches on the audio generator to read the "thousands" dial. As the generator frequency is varied, the reeds of the "thousands" row vibrate into contact with the spindle separately and successively until one is found which makes contact with one of the ten segments mounted spirally on the spindle surface. This short circuits the electromagnet coil and causes a change in the signal to which the observer is listening. The position of the tuning dial then indicates directly the position of the "thousands" pointer. In like manner the readings of the other pointers are ascertained.

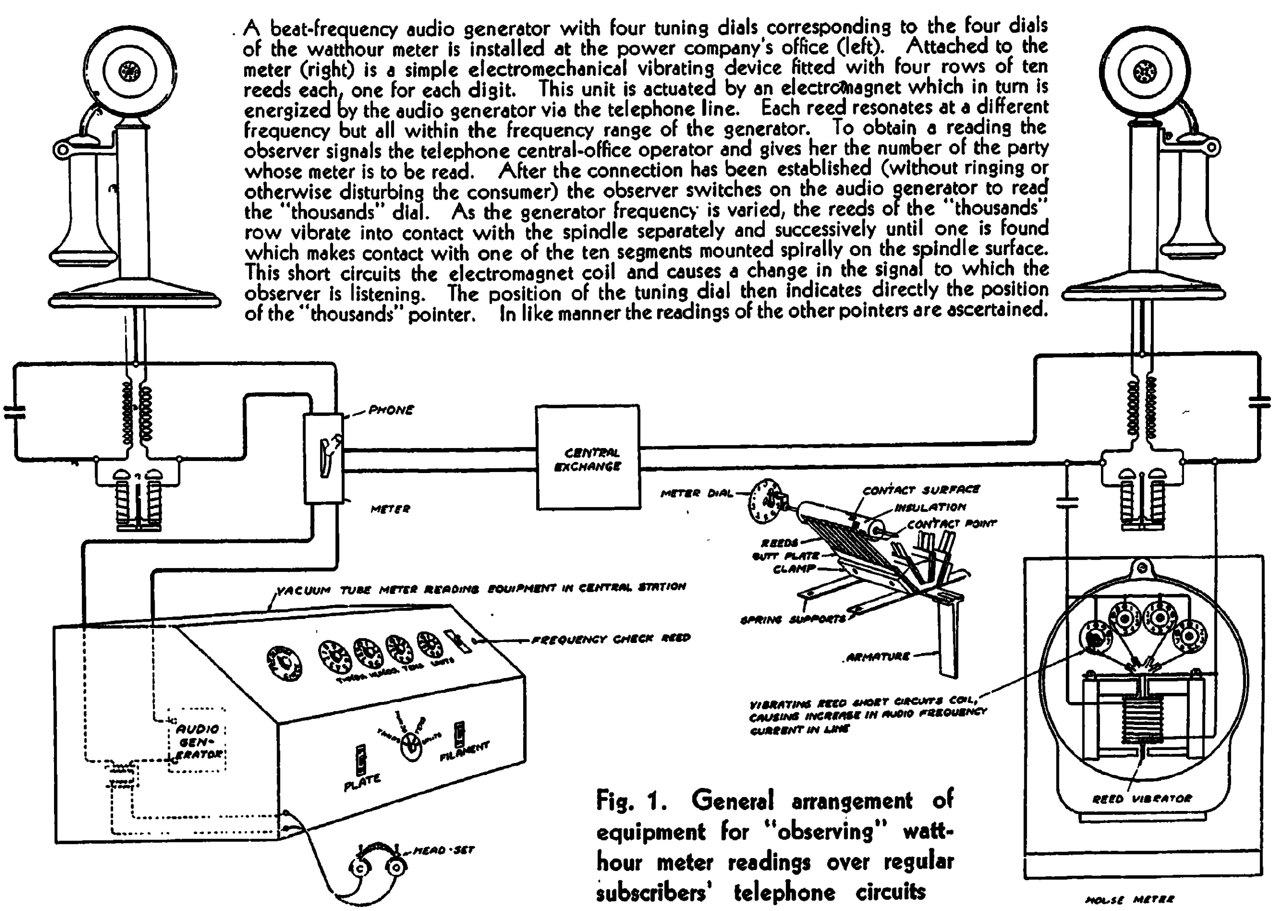

Fig. 1. General arrangement of equipment for "observing" watthour meter readings over regular subscribers' telephone circuits

reading quite obviously must justify itself from a cost standpoint. Average cost for reading a meter in a city district has been estimated at from 1.5 to 2.0 cents, and from 10 to 15 cents in a rural district. On the basis of these estimates the maximum justifiable investment for remote reading equipment is $4 for city and $30 for rural districts. An additional expense item would be involved in the use of the telephone company's lines. Also the fact that the plan postulates that each consumer is a telephone subscriber must be taken into consideration.

The general arrangement of equipment, together with the scheme of operation are indicated in Fig. 1, while in Fig. 2 may be seen a standard watthour meter rigged up for experimental purposes. The four tuning dials of the audio generator in the power company's office are arranged so as to indicate directly the positions of the four meter hands. Thus, after all four dials of the generator have been adjusted to "find" the positions of their respective meter hands, these tuning dials directly represent the watthour meter reading.

Several difficulties were experienced during the course of the experiments. One of the chief of these concerned the vacuum tube audio generator. Most of these difficulties were overcome, however, with the installation of a more stable and precise unit, and the provision of means for checking its accuracy. Variation in the frequency of response of the reeds due to wearing of the contact tips or temperature differences was found to be negligible. However, serious difficulties would be

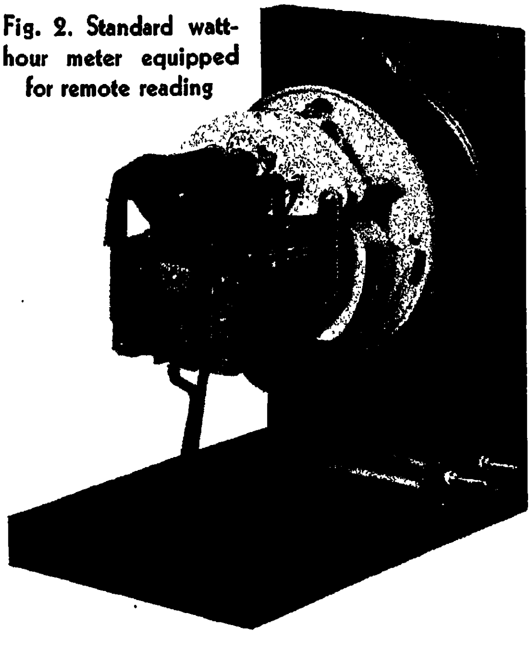

Fig. 2. Standard watthour meter equipped for remote reading

experienced in carrying out the scheme where party telephone lines are in use, or where machine switching exchanges are employed. Additional equipment no doubt would be required under these conditions.

Equipment and circuit arrangements described in the foregoing are mentioned merely as a suggestion of a future possibility. Engineering phases of the problem have been proved by extensive laboratory experiments to be capable of relatively simple solution, but of course the commercial application is quite another question and naturally would hinge principally upon the intercompany agreements that would be necessary before established communication channels could be put to such use.

Cable Temperatures at Variable Loading

Accurate methods, long available for calculating the temperatures in power cables during steady loads now can be supplemented by methods of calculating cable temperatures during fluctuating loads. Under favorable circumstances these give accuracies within 5 per cent. Further, the m thod is simple, and calculations can be made readily.

By
E. A. CHURCH
Associate A.I.E.E.

Edison Electric Illuminating Co. of Boston

MAXIMUM USE of the large investment in power cables can be made only if accurate information on the temperatures and loading limits of cables during variable loads is available. Although there are now fairly accurate methods for calculating the temperature rise when the load is steady, until recently no attempt was made to obtain even a moderately rigorous solution for the case of variable loading.

A point-by-point method of solution for variable loading based on the assumption that the temperature of the conductor rises exponentially with time was given in the JOURNAL of the A.I.E.E., October 1930, p. 855. This, however, is only approximately true and the theory presented below tends to show that the temperature curve rises faster at first, and then slower than the exponential law would allow, for example at 1 hr. after the load is applied.

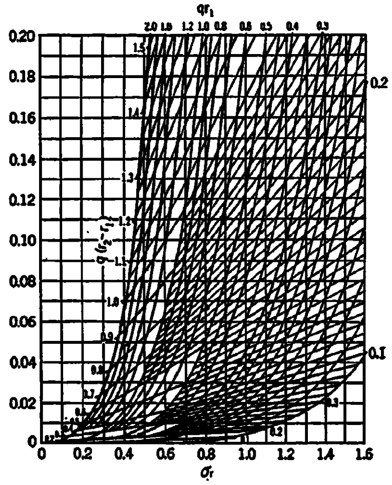

Fig. 1. Heat flow constant: $\sigma = i_2 k_1 - i_1 k_2$

$i_1 = I_0 \sqrt{j}\, q r_1 \qquad i_2 = I_0 \sqrt{j}\, q r_2$

$k_1 = K_0 \sqrt{j}\, q r_1 \qquad k_2 = K_0 \sqrt{j}\, q r_2$

By the use of Bessel functions, a rigorous solution of the problem of temperature rise from sheath surface to conductor is presented for single-conductor cables and three-conductor cables of shielded type H construction. Modifications of the cable constants allow the theory to be applied with reasonable accuracy to cables of standard belted construction. The heat flow cycle is resolved into harmonics and each harmonic solved separately for temperature at the conductor. Then the various harmonics of temperature are combined in their proper phase relation to obtain the temperature cycle. For purposes of assigning emergency ratings, a solution making use of the Fourier integral is derived for suddenly applied steady load.

SOLUTION FOR DAILY LOAD CYCLE

Derivation of the general equations for temperature in a single-conductor cable leads to the following simultaneous equations:

$$\frac{Q_0}{\pi} - j\,\frac{q_c^2 r_1^2 T_1}{S_c} = \frac{2}{S_i\,\sigma}\,(q_i r_1 \tau T_1 - T_2) \qquad (1)$$

$$\frac{D}{K}\,(T_2 - T_3) = \frac{2}{S_i\,\sigma}\,(T_1 - q_i r_2 \psi T_2) \qquad (2)$$

In the solution for three-conductor cable, eq. 1 remains the same, and eq. 2 is written as follows:

Based upon "Temperatures in Electric Power Cables Under Variable Loading" (No. 31-75) presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931.

$$\frac{D}{3K}(T_2 - T_3) = \frac{2}{S_i \sigma}(T_1 - q_i r_2 \psi T_2) \qquad (3)$$

where

T_1 = vector temperature at surface of conductor
T_3 = vector temperature at surface of insulation
T_3 = vector temperature of the air at the surface of the sheath
Q_0 = vector heat flow per conductor, equal to the $I^2 R$ loss
Q_1 = vector heat flow per conductor at inside surface of the insulation
Q_2 = vector heat flow per conductor at outside surface of the insulation, or at outside surface of the sheath if sheath losses can be neglected as they are assumed to be in eqs. 2 and 3
r_1 = inside radius of the insulation
r_2 = outside radius of the insulation
D = diameter of the sheath
q_c = $\sqrt{\omega C_c \rho_c S_c}$
q_i = $\sqrt{\omega C_i \rho_i S_i}$
ω = 2π × frequency of vector heat flow
C_c = specific heat of the conductor material
C_i = specific heat of the insulation material
ρ_c = specific gravity of the conductor material
ρ_i = specific gravity of the insulation material

The symbols σ, τ, and ψ represent complex constants, analogous to the general circuit constants of a transmission line, which depend on the constants and configuration of the cable. For ease in computation, charts of σ, τ and ψ based on Bessel functions have been prepared and are illustrated in Figs. 1, 2, and 3.

In carrying out any particular calculation, the watt loss in the cable is plotted for the load cycle assumed. This curve then is analyzed by well-known methods for its principal harmonics. The solution for temperature is obtained for each harmonic of heat flow and the results combined in their proper phase relation to give the resultant temperature cycle.

If the cable is installed in a duct and only approximate solutions are required, the value of T_3, the temperature of the air at the surface of the sheath can be assumed constant at the maximum value obtained over a 24-hour load cycle. Usually when the cable is installed in an ordinary duct bank T_3 will vary from 20 to 30 per cent of the total variation in temperature at the conductor. If T_3 is considered constant, its value becomes zero in eqs. 2 and 3, merely adding to the steady state component of the total temperature at the conductor, which is computed by well-known methods. Then the value of T_1/Q_0 will be constant in both phase and magnitude for any given cable. Hence, tables of T_1/Q_0 for any given cable may be compiled for the principal harmonics. These may be combined in their proper phase relation to obtain a solution for any load cycle.

On account of the effect of adjacent cables and the uncertainty of the constants of the duct bank, the best method of obtaining the air temperature at the sheath surface is by means of a maximum-reading thermometer surrounded by a thin shield of heat insulating material. It is generally conceded that the temperature in the duct outside the lead sheath is nearly the same throughout the space between the sheath and the duct and can be considered so in the solution for steady heat flow. Since the air has a very low thermal capacity, its temperature will follow the variations in the lead sheath very closely in phase. Hence, if the maximum value of this air temperature throughout the load cycle considered can be obtained, it may be added directly to the maximum temperature rise between this air and the conductor to obtain the total rise. The error caused by these temperature components being out of phase will be small, since the total variation in the air temperature is only about one-quarter of the total.

SOLUTION FOR A STEADY LOAD SUDDENLY APPLIED

The solution for a steady load suddenly applied is as follows:

$$T_0 = \frac{2\,Q_0}{\pi} \int_0^\infty \delta_r \frac{1}{\omega} \sin \omega t \, d\omega \, . \qquad (4)$$

where

T_0 = the temperature of the conductor at any time t after the steady load is applied
δ_r = the real part of the expression

$$\delta = -j\left\{\frac{\gamma}{\pi q_c r_1}\right\} \times \left\{\frac{1}{\dfrac{q_i r_1 \tau}{S_i \sigma} - \dfrac{\eta}{S_i \sigma (S_i \sigma D + \eta q_i r_2 \psi)} - \dfrac{q_c r_1 \gamma}{S_c}}\right\}$$

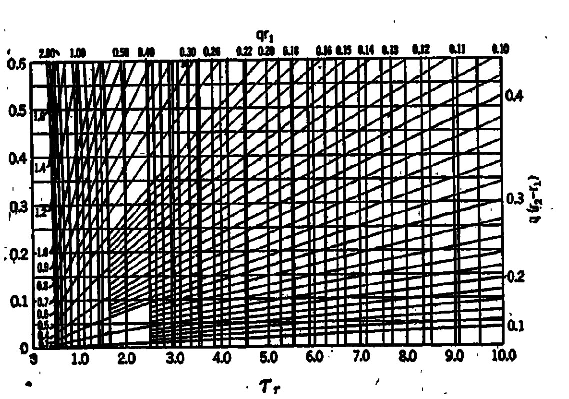

Fig. 2. Heat flow constant: $\tau = i_1' k_2 - i_2 k_1'$

$i_1' = \sqrt{j} I_0' \sqrt{j} q r_1 \quad k_2 = K_0 \sqrt{j} q r_2$
$k_1' = \sqrt{j} K_0' \sqrt{j} q r_1 \quad i_2 = I_0 \sqrt{j} q r_2$

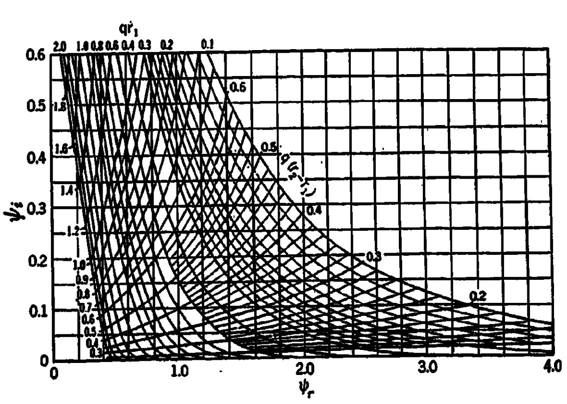

Fig. 3. Heat flow constant: $\psi = i_2' k_1 - i_1 k_2'$

$i_2' = \sqrt{j} I_0' \sqrt{j} q r_2 \quad k_1 = K_0 \sqrt{j} q r_1$
$k_2' = \sqrt{j} K_0' \sqrt{j} q r_2 \quad i_1 = I_0 \sqrt{j} q r_1$

where

$\gamma = j q_c \; r_i/2$ (approximately)

$\eta = 2\,K$ for a single-conductor cable in still air

$\eta = 6\,K$ for a three-conductor cable in still air

The expression

$$\frac{1}{\omega}\,\delta_r \sin \omega t \, d\omega$$

is much too complicated to integrate by formal means, but it may be integrated readily by graphical methods, as with a planimeter. The value of the function is plotted for different values of t and integrated with respect to ω. Integrating from 0 to ∞ offers no difficulty here since the function converges rapidly as the value of ω is increased.

STANDARD BELTED CABLE

The equation for obtaining the steady state temperature rise of the conductor above the outside surface of the insulation has been given by R. W. Atkinson (Cable Geometry and Calculation of Current Carrying Capacity, A.I.E.E. TRANS., Vol. XLII, 1923, p. 600) and by D. M. Simmons (Calculation of Electrical Problems of Transmission by Underground Cables, *Electric Journal*, August 1925, p. 366). This equation is as follows:

$$(T_1 - T_2) = \frac{Q_0\, S_i\, G}{2\,\pi} \tag{5}$$

where G is the geometric factor.

For the shielded cable, the geometric factor is given by D. M. Simmons (Calculation of Current Capacity of Type H Cable, *Electric Journal*, Feb. 1926, p. 59) as follows:

$$G = l\,n \frac{r_2}{r_1}\,.$$

For the cable under consideration, obtain values of G from the curves given in the first of the two articles by Simmons just referred to, and solve for an equivalent S_i. In average cables this equivalent S_i is about double the true value for the insulation under consideration. This value of S_i may be used in eqs. 1 and 3, to obtain an approximate solution which it has been found gives the result within 5 or 10 per cent of the true values as far as the variable component of temperature is concerned. The rigorous solution for standard cable which would involve much more labor would have no value as long as the cable constants cannot be obtained with any greater accuracy.

PROBABLE MAGNITUDE OF ERRORS

The change in resistance and dielectric loss with change of temperature for ordinary load cycles will not be over 5 or 6 per cent. If it is desired to take this into account a correction may be applied to the watt loss curve corresponding to the estimated temperature at that time. The value of temperature rise to be assumed in making this correction can be taken as half the ultimate temperature rise produced by the average watt loss over an hourly period. This is based on the fact that in average cables the temperature at the conductor reaches about half its ultimate temperature within an hour after a steady load is applied. The error introduced by change in resistance will be less than 0.5 per cent if this correction is made.

For sector conductors, the heat flow will be more concentrated around the regions of smaller radius but the error in neglecting the effect of sector shape will not be over 1 or 2 per cent.

Large conductors show considerable proximity effect when three conductors are concentrated in the small area inside the cable sheath. When three-phase current is flowing the current tends to crowd to the inside of the cable sheath. However, under the assumed condition of uniform current distribution the total variation in temperature through the conductor is only 1 deg. for ordinary load cycles. The smallness of this variation is due to the high heat conductivity of the copper. Hence, if the proper equivalent a-c. resistance is used for the cable in question, the error in temperature due to unsymmetrical current distribution will not be over 1 per cent. Of course this assumes that all the losses, excluding dielectric losses, are in the conductor. There are undoubtedly some losses in the sheath even in three-conductor cables, especially where large conductors are close to the sheath as they are in shielded cables. Not knowing definitely where all these losses are located, the conservative method would be to assume them all in the conductor.

Neglecting the temperature drop in the copper foil around the conductors in shielded cables introduces about 8 to 9 per cent error in the steady state solution. A similar error will be introduced in the solution for variable load. This error will be minimized in the total temperature rise if the steady state component of the temperature cycle is computed taking this drop in the foil into account as indicated in the second article by Simmons, previously referred to. Neglecting the heat storage in the lead sheath partially compensates for this error.

The over-all error in the method is thus not over 5 per cent and is probably much less if the watt loss curve is corrected for temperature. It is doubtful if the value of the insulation heat conductivity is known within 5 per cent plus or minus, so that it is useless to expend the labor necessary in obtaining greater refinement.

By means of computations based on this theory the temperature curve for any cable and load cycle may be calculated readily without excessive labor and with accuracies well within the accuracy of the cable constants. The effects of day-to-day changes in load cycle die out in a few hours so the theory can be applied to any day of the week with little effect from the previous day's cycle. Short-time overload ratings of any duration may be added to any initial loading with confidence that the calculated temperature rise will not be exceeded.

Progress is the Way Out of Depression

Intelligent self-interest, individually applied with sincerity of purpose toward the solution of every-day problems, is recommended as the most efficacious way out of present economic troubles. This is the fifth article of The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"

By
ARTHUR W. BERESFORD Secy., Natl. Elec. Mfrs. Association

THE CURRENT economic depression cannot be ascribed to any single cause, nor will a panacea be found in righting any single wrong. Moreover, there is little of value at the moment in attempting to isolate and correct the major causes. They will emerge gradually from the present chaos as time provides a perspective; their evaluation will furnish the basis for long-time planning which should operate against recurrence. But this long-time planning, valuable as it would be, cannot be done now. The problem is too vast, the factors too many, and their inter-relations too complicated to be grasped and ordered by the human mind. So, in place of the co-ordinated effort which would be the outcome of a master plan, we must use what we have.

What have we? We have millions of men and women, each one of whom comprehends clearly some small part of the whole. If each of them spends each day in doing his individual best toward moving in the direction each knows to be right those things that each one understands, there is no fear of the outcome. There may be a wastage which would be absent in a master plan, but the whole will move forward surely and before a master plan, however imperfect, could be evolved.

This is an old and simple doctrine. Anyone can think it, and unfortunately it carries none of the exaltation that comes from the spectacular. But it is sound doctrine, and in the measure in which it is practised will be found the rate at which we will progress.

Human progress is not the result of the effort of the outstanding few, be they statesmen, industrialists, scientists, engineers, or inventors. It is the cumulative effect of the daily effort of the millions. The leaders but guide or accelerate it. The summation of the thousands of millions of small things is greater than the greatest large thing that the human mind can grasp. The combined effort of millions of average human beings will outweigh the most daring conception of the greatest vision the world ever has known. And these millions will put forth that effort, not as a result of ordered consideration, nor even by reason of instinctive realization, and least of all from any altruistic motive, but purely and wholly from self-interest. The efficiency of the process will lie in the degree in which that self-interest is intelligent; the hope of efficiency rises from the fact that there is growing comprehension that self-interest must be intelligent.

The average manufacturer perceives today that his interest and that of his workmen is a common one. He does not prosper if they do not. This long has been the conviction of the few, but it required the current condition to bring this realization home to the many. And again will be demonstrated the workings of this simple doctrine of mass effect. Eighteen months have increased the *quantity* of understanding more than the preceding eighteen years. Further, there has been made manifest the need for balance in the economic forces which make up our involved civilization. A force is constructive or destructive in the degree that it is or is not controlled. Production, whether of foodstuffs, of raw materials, or of finished goods, is constructive if balanced against consumption. It is destructive if unbalanced and guided only by unintelligent and immediate self-interest. Surely the past months have brought to the many a realization of this simple fact. From this realization there will as surely follow provision for assuring that balance.

The means are not yet clear, and a period of trial and error is to be expected before an approximate solution is found. However, the mere fact that stabilization of employment is economically dependent on controlled production, and consumption dependent on stabilized employment, will unite all elements in a common demand for that solution. This would not have been possible five years ago; but the thinking forced on the many in the past two years has brought an understanding of fundamentals which makes it not merely possible, but certain, and for the near future.

The present conditions are difficult to contemplate with mental serenity and undisturbed confidence, but they carry more of ultimate value than the prosperous years that preceded them. The growth of understanding by the many will form the foundation for a new and greater progress, for a civilization such as the world has not yet known. In this progress the engineer and the engineering method of basing procedure on determined fact will have a major part. The saying that "through adversity we progress" again will demonstrate its truth.

Editor's Note: Pursuant to the invitation of The Engineering Foundation, the editors will be happy to receive comments, suggestions, criticisms, or discussions pertaining to this or the other articles published in this series.

Extinguishing the Short A-C. Arc

Three articles are presented herewith, following a common introduction, all on the same general subject, namely, the extinction of the short a-c. arc at low voltages in air. The importance of this subject is emphasized by the increasing use of the low-voltage a-c. distribution network and of a variety of equipments for interrupting circuits in air.

SHORT ARCS are employed in all circuit interrupters operating in a-c. circuits of less than 150 volts, and also are made use of in the deion air circuit breaker, where many short arcs are placed in series for operation at high voltages. Of equal importance is the behavior of an arc during a short circuit in low-voltage a-c. cables. The low-voltage network which is finding such great popularity as a system of distribution in metropolitan areas is dependent upon the capacity which it enjoys for self-clearing of faults without interruption of the power supply. This system insures that at any point of fault there will be sufficient current to melt apart any contacting metallic conductors and start an arc, and the low voltage which has been used on most networks insures that the arc will be extinguished quickly at a normal zero of current.

The first article, that by Attwood, Dow and Krausnick, presents in considerable detail the results of a very comprehensive group of tests on the reignition of a-c. arcs in air for different rates of build-up of the circuit voltage across the arc space. Throughout their tests the arc was produced by a current of 25 amperes at 660 volts, 60 cycles between flat copper electrodes placed ¾ in. apart in air. Although a strict interpretation of their results must be confined to low-current arcs, the very large number of oscillograms which they carefully have taken, studied and presented, throw considerable light on exactly what happens during the extremely short period when the arc current is at zero.

The second article, by Browne, presents the results of a group of experiments on the more common types of stationary arcs with molten electrodes, for the purpose of determining the influence upon the arc characteristics of such parameters as electrode material, current strength, and length of arc. The third article, by Slepian and Strom, is concerned principally with the effect which cable insulation has on the extinguishing of faults in low-voltage a-c. networks, due to the deionizing action of gas blasts formed by the decomposing insulation.

The fundamental theory upon which all three of these papers are based is identical. The continuance of the a-c. arc is believed to depend upon repeated reignition for each new half cycle after a current zero. The extinction of the arc has been shown to depend upon the outcome of "a kind of race" between two opposing processes taking place within a very short period after the current reaches zero. The first is the building up of voltage across the arc space tending to cause the arc to reignite, and the second is the diminishing of the conductivity of the arc space, or the increasing of its dielectric strength, tending to prevent the arc from restarting. The first depends upon circuit constants and upon circuit conditions existing at the current zero, and so theoretically can be calculated according to well-known principles, although this may be rather difficult if the circuit is not sufficiently simple. The second process, and the one with which these articles are most concerned, depends upon the characteristics of the arc itself. These are exceedingly complex and as yet understood to only a very limited extent. This building up of dielectric strength depends upon conditions internal to the arc space, such as the nature and geometric arrangement of electrodes, the nature of the gas, presence of magnetic fields, and gas blasts.

According to the modern theory of conduction in gases, the rapid recovery of dielectric strength by an arc space immediately following a current zero must be due to the disappearance of the ions which are required for the conduction of the arc current. Ions disappear from the arc space by direct recombination in the arc space itself; discharge to the electrodes; recombination on surrounding walls or in surrounding cooler gases; recombination in cooler gases mixed turbulently into the arc space by gas blasts; and formation of an almost completely deionized layer adjacent to the cathode by the action of the ions of the growing impressed electric field. In short arcs, discharge to the electrodes appears to be most important, and in longer arcs, recombination on surrounding walls and gases. The importance of the gas blast in practical devices only recently has begun to be appreciated.

Although the theory upon which all three of these articles are based is identical, the terminology varies somewhat. Figs. 2 and 8 of the first article and Fig. 6 and 12 of the other two articles, all represent the increasing dielectric strength of the arc space as a function of time. This increasing dielectric strength is referred to by Attwood, Dow and Krausnick as the "reignition-time locus," while Browne does not coin any special phrase to designate it. Slepian and Strom refer to this quality as the "arc reignition characteristic." The latter also refer to the tendency of the circuit to build up voltage across the arc space as the "circuit reignition characteristic."

The conclusions presented by these authors regarding the factors aiding arc extinction are most interesting, and in some cases striking. In general, they are in agreement, although the first two articles differ somewhat on the effect which length of arc has on the recovery of dielectric strength by the arc space; and the first article also indicates that the "reignition-time locus" should be represented as an area rather than as a curve. Whether or not these apparent discrepancies result from the fact that the first article considers arcs of relatively low current values, 25 amperes, while the second reaches into currents of a few thousand amperes, may possibly be explained by the further tests on short arcs which doubtless will be made in different laboratories.

I—Oscillograph Tests on Low-Current Arcs

REIGNITION OF A-C. ARCS being dependent upon the arc-voltage relations during current zero, a study based on some 200 cathode-ray oscillograms has been made of the voltage and current relationships near the cyclic current zero in arcs between metallic electrodes.

For experimental purposes a 25-ampere 660-volt 60-cycle arc between flat copper electrodes spaced ¾ in. apart in air was utilized. The circuit used (see Fig. 1) consisted of a transformer of voltage e_s connected to the arc through a reactor L, with its small (but not negligible) distributed capacity C_L. The voltage e_a of necessity was measured by a cathode-ray oscillograph because of the extremely rapid variations. Time relations existing between the supply voltage e_s, the arc voltage e_a, and the arc current i_a are shown also in Fig. 1. During approximately 95 per cent of each half cycle the arc current is a sine wave lagging practically 90 deg. behind the supply voltage, while the arc voltage remains constant. It is upon the remaining 5 per cent of the half cycle that the major part of this investigation has been concentrated.

Eventually the arc current reduces sinusoidally to a small value I_1 (order of 0.1 ampere) at which value it suddenly fails, falling sharply to zero, where it remains until the arc again is made with current in the opposite sense. During this short period the supply voltage is practically constant ($e_s = E$).

The current i_L in the inductance cannot cease flowing instantaneously and therefore surges into the distributed capacity. During the period of current zero (from 0 to t_1) the voltage e_a may be computed by the usual circuit equations, which are shown also in Fig. 1. In the circuit used, L was 0.066 henry and C_L was 440 $\mu\mu$f.; with these values a cosine voltage having a frequency of 29,400 cycles per sec. is set up across the arc terminals.

At time t_1 when the electrode voltage has reached a value of perhaps 400 volts in the positive direction, the arc space breaks down and the voltage drops rapidly to the glow value of 350 volts, remaining constant for a period varying from an extremely brief interval to several hundred microseconds. During the glow period (t_1 to t_2) the arc current rises slowly. At time t_2 when the current through the inductance has risen to a value sufficient to maintain an arc, the electrode voltage drops sharply from the 350-volt glow value to approximately 100 volts for the arc proper; the arc current then resumes its sinusoidal character. Particular attention is called to the negative dip in the electrode voltage. This dip is due entirely to failure of the arc current at some definite value prior to the time when it would become zero had it continued along its sinusoidal variation.

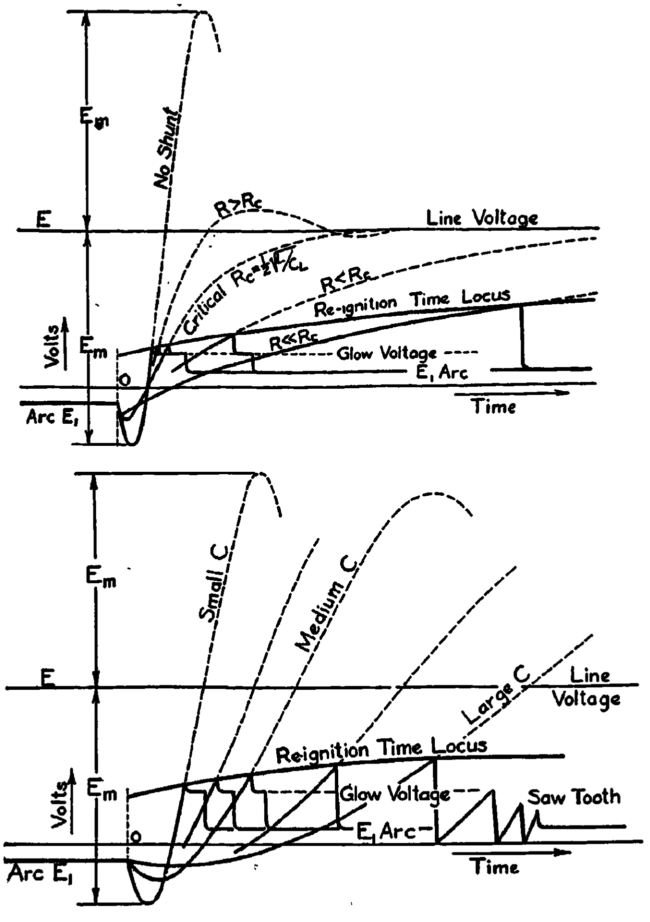

Fig. 2. Effects of resistance (above) and capacity (below) upon arc reignition time

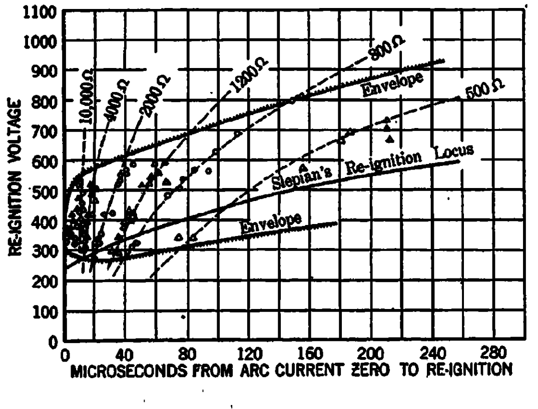

Fig. 3. Actual measurements of reignition voltage-time relations for various arc shunt resistances

If the arc electrodes are resistance-shunted, the circuit equations show that during the zero-current period, the rise of voltage across the electrodes will be slowed down materially. With more time available for deionization the electrode voltage must rise to a higher value in order to break down the arc region. The effect of varying this shunt resistance may be seen in Fig. 2. The line drawn through the breakdown values may be called the *reignition-time locus*. This locus shows the rapidity with which the deionization process in the arc space proceeds during the zero-current period.

For an arc shunted by resistance greater than the critical resistance, the electrode voltage e_a may be computed from equation (1), which represents a damped sine wave.

$$e_a = E - e^{-\frac{1}{2RC_L}t}\Bigl[(E - E_1)\cos\omega t + \frac{1}{\omega C_L}\Bigl(-I_1 + \frac{E - E_1}{2R}\sin\omega t\Bigr] \qquad (1)$$

where $\omega = \sqrt{\frac{1}{LC_L} - \frac{1}{4R^2C_L^2}}$

$$R > \frac{1}{2}\sqrt{\frac{L}{C_L}}$$

For values of resistance less than the critical amount,

$$e_a = E - e^{-\frac{1}{2RC_L}t}\Bigl[(E - E_1)\cosh\beta t + \frac{-I_1 + \frac{E - E_1}{2R}}{\beta C_L}\sinh\beta t\Bigr] \qquad (2)$$

where $\beta = \sqrt{\frac{1}{4R^2C_L^2} - \frac{1}{LC_L}}$

$$R < \frac{1}{2}\sqrt{\frac{L}{C_L}}$$

For still smaller values of resistance equation (2) reduces to the simpler form of equation (3)

$$e_a = E - e^{-\frac{Rt}{L}}[E - (E_1 + I_1R)] \qquad (3)$$

For resistance shunts greater than the critical value it may be noted that the arc-voltage rise takes the form of a damped sine wave. For resistances smaller than the critical value, the voltage-rise curve is a hyperbolic function of the circuit constants and time, and is asymptotic to the line voltage E. The critical resistance proved to be 6,125 ohms for the circuit constants used in this study.

Equations shown in Fig. 1 apply also to the voltage and current relations in a capacity shunted arc if the shunt capacity C is used in place of the now negligible distributed capacity C_L. Inasmuch as C is usually much greater than C_L the cosine curves of electrode voltage rise are much slower than in the non-shunted arc. This point is illustrated in the lower part of Fig. 2.

In Fig. 3 are plotted the actual reignition voltage-time points as obtained from oscillograms for a number of different resistance shunts across the arc. The dashed curves indicate the voltage rise across the electrodes. Particularly worthy of note is that reignition may occur anywhere along the voltage-rise curve between the limits set by the upper and lower parts of the envelope. There is no single value of voltage at which reignition takes place, but a general upward trend with time is shown by the reignition envelope. A set of tests using capacity shunts led to the development of an envelope which is identical with the envelope shown for the resistance shunts.

Significance of the three regions into which the envelope divides Fig. 3 is perhaps most clearly explained as follows: when the rising electrode voltage is below the lower branch of the envelope, reignition cannot take place; inside the envelope region reignition may take place, but it invariably occurs by the time the upper envelope is reached. For a low-resistance shunt such as the 500-ohm case shown in Fig. 3 the electrode voltage may rise to the line voltage without reignition taking place. This has been observed frequently.

By using another method, Slepian (*Extinction of a Long A-C. Arc*, A. I. E. E. TRANS., Vol. 49, p. 421) obtained previously a reignition locus which is drawn on Fig. 3 for the sake of comparison. It is believed that his curve would coincide with the lower branch of the envelope if test conditions were identical.

Efforts to locate the cause of the variability of restriking voltage so far have been fruitless; it may be due, however, to the presence of impurities in the surfaces of the electrodes over which the arc moves, though ever so slowly.

In Fig. 4 are shown four cathode-ray oscillograms of the electrode voltage during the current zero period, each oscillogram showing a number of curves taken at least 20 cycles apart. These illustrate the changes occurring when the arc shunt resistance is varied. With a 10,000-ohm shunt, the cosine voltage wave is much in evidence; with resistances below the critical value (6,125 ohms) the hyperbolic curve may be observed. The 1,200-ohm case shows a rapidly rising voltage with reignition occurring at a practically constant value, whereas in the 4,000-ohm case the voltage rise is much slower with a decided variability in the reignition values. With 0.1-μ f. shunt a cosine voltage rise may be seen with a somewhat variable reignition voltage. The "saw-tooth" voltage peculiar to a capacity shunted arc is caused by the alternate charge and discharge of the shunting condenser, and hence occurs only with relatively large values of shunt capacity.

In the 10,000-ohm case it may be noted that two types of negative dip may occur. A peaked negative dip indicates that the arc current failed at a slightly larger value than for the curved negative dip; the negative voltage then rose to a value sufficient to cause glowing before the real current zero period was reached.

Application of this material to the action of a circuit breaker as it opens, drawing longer and longer arcs for each succeeding half cycle, is illustrated in Fig. 5. Three electrode-voltage curves and three expected reignition loci are plotted for three successive half cycles. Because the electrode voltage increases with increasing arc length, causing any given value of recovery voltage to occur at longer periods of time from the instant of arc failure, curves of this voltage start at different negative values.

The beginning points of the arc reignition curves are drawn higher for each succeeding half cycle because the greater electrode spacing should require a somewhat greater short-time value of breakdown voltage. The slopes of the arc reignition curves are made steeper for each succeeding half cycle because deionization should be expected to take place more rapidly with long than with short arcs. The crossing of curves 1, and again of curves 2, indicates successive half-cycle reignitions where the two curves meet. The fact that curves 3 do not intersect indicates that deionization has taken place with such rapidity that the voltage-rise curve never will meet the reignition curve and consequently, reignition no longer will take place.

Fig. 5. Expected reignition voltage-time relations for capacity arc shunts with increasing electrode spacing, simulating the arc conditions which exist when a circuit breaker opens

It is thought that loads on a line located near a circuit breaker which opens will operate upon the breaker in much the same manner as the shunt resistances discussed previously, tending to cause a delay in the rise of electrode voltage toward reignition, with a consequent lessening of the expected severity of circuit-breaker duty. It should be emphasized, however, that Fig. 5 illustrates qualitative action only. Care should be taken not to generalize too far into high-voltage or large current situations from the results here described.

II—Various Factors Aid Extinction of Arcs

By
T. E. BROWNE, JR. Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

EXPERIMENTS to determine the influence of such parameters as electrode material, current strength, and arc length on the characteristics of the more common type of stationary arcs with molten electrodes, have given results not previously expected. Simplified calculations made by Slepian a few years ago based on the theory that ions are lost from the arc space only by direct ion recombination, predicted a manner of recovery of dielectric strength substantially the same as that actually revealed by experiments made on cold electrode arcs at about the same time. The rate of recovery of voltage across the arc space following a current zero was controlled by shunting the arc with resistance, and the maximum allowable rate of rise of voltage was determined from the maximum value of shunting resistance at which the arc would just be extinguished after one-half cycle.

In general, the experiments recently completed show that the manner of dielectric recovery following a current zero of short, stationary a-c. arcs with molten electrodes conforms to the predictions of Slepian's theory and is similar to the recovery of rapidly moving cold electrode arcs previously investigated. That is, for electrodes whose boiling temperatures are below the temperature required for appreciable thermionic emission, the ability to withstand 100 volts or more was recovered within a few microseconds after a current zero, and further dielectric strength was regained at a very much lower rate. This is shown by the curves of Fig. 6.

As predicted, the initial very rapidly recovered dielectric strength was found to depend solely on the electrode material and gas medium, and not at all on any other conditions within the limits investigated. The further more slowly recovered dielectric strength did not, however, prove to be independent of such conditions as arc length and current magnitude, as Slepian's approximate theory predicts that it should. This simply indicates that factors neglected in the simplified theory, such as diffusion of ions to the electrodes and to the surrounding air, the electric field, and temperature variations, are not actually negligible.

EFFECT OF ARC LENGTH

The effect of length of the arc on recovered dielectric strength was found to depend on the electrode material used. In the first series of tests made with brass electrodes, the effect of arc length was very striking and at first sight seemed paradoxical. As shown in Fig. 6, the dielectric recovery of a 0.158-cm. arc was considerably more rapid than the recovery of an arc of twice that length under otherwise similar conditions, indicating that the shorter arc is easier to extinguish than the longer. This effect is shown in a still more striking manner by plotting the initial slopes of critical applied voltage curves, like those shown dotted in Fig. 6, against arc length. This has been done in Fig. 7 for extinction at 450 volts, and shows that the effect extends up to five cm. or more, but is most pronounced at lengths of less than one cm. A similar but still more pronounced effect was observed with metals of lower boiling point than that of brass. With electrodes of the higher boiling metals, however, such as copper, iron, and tungsten, the effect was very much less and reversed its direction at the shorter lengths. This is illustrated by Fig. 8, which is the curve of Fig. 7 for brass, redrawn to a different scale and compared with similar curves for mercury, zinc, copper, iron, and tungsten-electrode arcs. The curves for copper and

From "Extinction of Short A-C. Arcs," (No. 31-90) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1981.

iron are seen to coincide practically with that for brass near five mm. and above and to exhibit the same falling characteristic above about four mm.; but below this length, instead of rising rapidly with diminishing length as with the lower boiling metals, they fall off again; the curve for iron rapidly approaching zero and the curve for copper falling and then apparently tending again to turn upward at the shortest lengths investigated. With the very refractory metal tungsten, the curve is much lower even than with copper and iron, but still appears to reach a maximum at some arc length less than one cm. and to fall off with increasing length above that.

EFFECT OF ELECTRODE MATERIAL

As already shown, the behavior of a short a-c. arc depends very largely on the material of the electrodes. Fig. 9 shows the results of a series of experiments on 300-ampere, 60-cycle, 450-volt arcs, 0.079-cm., 0.158-cm., and 0.316-cm. long, using various metallic elements as electrodes. The critical initial rate of rise of voltage as measured by the critical shunting resistance for arc extinction is plotted in each case against the boiling point of the element. The interesting and surprising feature of this graph is the definite tendency for the points at each arc length to fall on intersecting straight lines. This approximately linear manner of variation with boiling point applies to all the metals for which results were obtained except mercury, which has values at about twice those required to fit the straight lines, and magnesium, aluminum, manganese, molybdenum, and tungsten (not shown), which either form stable refractory oxides or themselves boil at high enough temperatures for copious thermionic emission, thus preventing the immediate recovery of dielectric strength which characterizes the non-refractory metal arcs.

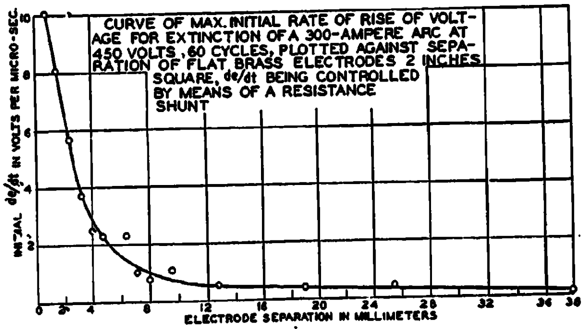

Fig. 7. **Initial slopes of critical applied voltage curves for extinction at 450 volts**

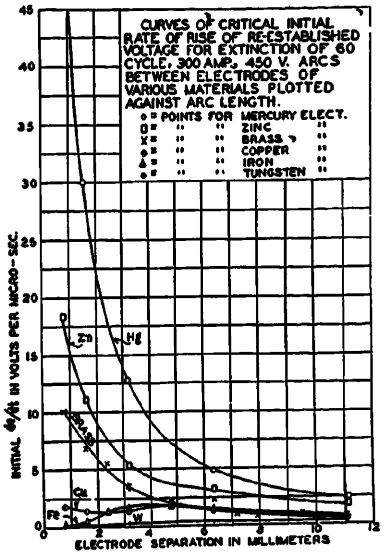
The performance of aluminum, copper, and brass-electrode arcs is shown comparatively in Fig. 10, in the form of curves of critical initial rate of rise of reestablished voltage plotted against the effective circuit voltage at which the values were obtained, other conditions than voltage remaining the same. Remembering that the ordinates of any one of these curves may be considered as a measure of the speed with which the arc space regains the ability to withstand voltages equal to the maxima of sine waves having the effective values given by the abscissas, it may be seen that 0.158-cm. arcs with aluminum electrodes require a very much longer time to recover ability to withstand a given voltage than do arcs of similar length between copper electrodes, and that 0.158-cm. copper-electrode arcs in turn recover dielectric strength very much more slowly than do 0.158-cm. brass-electrode arcs, other conditions being equal. The rapid rise of all of these curves at the lower voltages is attributed to the approach of the maximum voltage values to the minimum dielectric strength of the cathode-space charge sheath, which is recovered in practically zero time. This initially-recovered dielectric strength is approximately 160 volts

Fig. 8. **Effect of electrode separation on arc characteristics**



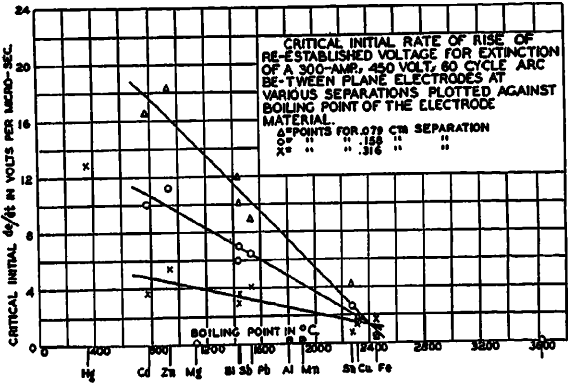


Fig. 9. **Effect of boiling point of electrode material on arc characteristics**

(maximum) for both copper and aluminum arcs, but is nearly 230 volts for brass-electrode arcs. Because of the scale used, the upper portions of the curves for copper and brass are not shown in this figure.

Effect of Current Magnitude

The simplified theory already referred to, predicted that the dielectric recovery of a short arc space should also be independent of magnitude of the arc current, but this prediction depended on the assumption that ionic diffusion to the surrounding air is negligible, which can be true only if the diameter of the arc is large in proportion to its length. Even for arcs only 0.158 cm. long, this condition is approached only at currents of more than a thousand amperes or so; therefore independence of current magnitude may be expected only with currents of this order. Fig. 11 shows this to be the case for a 0.158-cm. copper arc at 450 volts; current variations produce little change in the rate of dielectric recovery above 1,500 amperes, but below this value, decreasing the current causes a rapid increase in speed of dielectric recovery. Below about 150 amperes, the behavior of the arc becomes increasingly erratic so that definitely consistent values of a critical initial *d e/d t* were very difficult or quite impossible to determine. Tests made by F. C. Todd with the cathode-ray oscilloscope show that the restriking voltage of continually restriking arcs is extremely variable when the current is as low as 90 amperes.

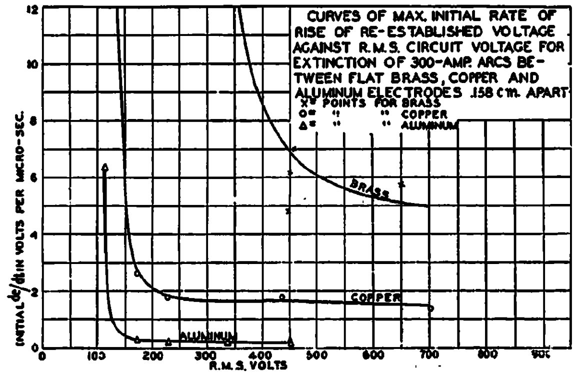

Fig. 10. Effect of circuit voltage on arc characteristics

Application to Engineering Practise

In view of the results herein presented, some suggestions may be made with regard to the construction of low-voltage circuit interrupting apparatus, where extinction of low-voltage a-c. arcs resulting from faults is important. Because of the marked superiority in short arcs of brass electrodes over copper or aluminum electrodes with regard to speed of recovery of dielectric strength at current zero, it would seem advisable to use brass for the contact-breaking parts of low-voltage switches working near their limit.

The suggestions in regard to the use of brass, copper and aluminum may apply with even more force when considering a material for conductors in secondary distribution networks than they do to switch construction. Thus it is suggested that the permissible operating voltage of such networks might be raised if brass conductors were used. These results, however, must be interpreted with caution when applying them to a problem having such varied practical aspects. Where the conductor material would also act as the electrode in case of a fault, it should be noted in Fig. 8 that the difference in favor of brass over copper applies only when the length of the arc is less than 5 mm. Consequently, if the arc would usually be longer than this, brass would probably be no more effective than copper or aluminum in aiding its extinction.

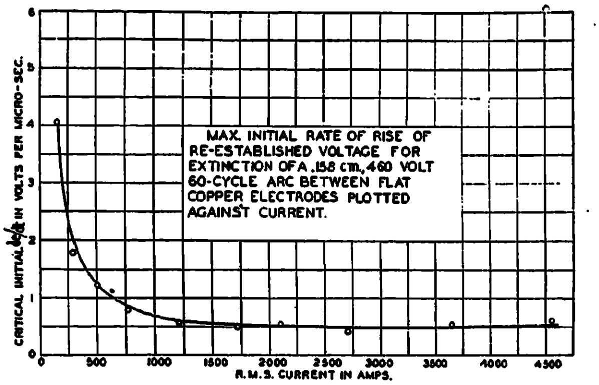

Fig. 11. Effect of current magnitude on arc characteristics

It may be noticed, also, that there is a discrepancy between practical experience with faults in secondary networks and the results given here, in that faults commonly are cleared on networks as high as 230 volts r. m. s. whereas in the laboratory, high-current copper-electrode arcs 0.158 cm. long could be easily maintained at as low as 113 volts. This may be due to less severe circuit conditions in the case of the practical network, caused by a fairly high power factor on short circuit and the presence of distributed capacitance of the cables and of shunting resistance in the form of connected lighting load, all of which tend to decrease the rate of recovery of voltage across the arc space at a current zero and so allow time for deionization of the arc and recovery of dielectric strength. Probably of more importance, however, is the deionizing action of gases resulting from burning of the cable insulation, the action of which is similar to that of gases from the decomposing oil in an oil circuit breaker.

III—Insulation Material Aids Extinction of Cable Arcs

By
J. SLEPIAN
Fellow A.I.E.E.

A. P. STROM
Associate A.I.E.E.

Both of the Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

A CLOSE STUDY of the type of arcs occurring with faults in low-voltage a-c. networks and the method by which they are extinguished has brought out several striking conclusions. It has been found that short arcs between copper electrodes and not adjacent to insulation are inadequate to meet the fault-clearing requirements of low-voltage a-c. networks of more than 130 volts. Actual low-voltage networks of voltage higher than 130 depend for extinction of arcs upon the strongly deionizing action of gas blasts coming from decomposing adjacent insulation. As suggested by this result, it has been found also that the extinction of arcs in cables is strongly affected by the closeness of the insulation to the arc. Also, inorganic insulating materials giving off non-combustible gases have been found to be effective in aiding arc extinction, and of the various inorganic materials tried, boric acid was the best. Further, where organic insulation has been charred, it may be expected to lose its property of aiding arc extinction.

The Short Arc Without Gas Blast

Test curves of the recovered dielectric strength of the arc space, or "arc reignition characteristic," are shown in Fig. 12. It will be noted that up to a certain point there is an almost instantaneous recovery by the arc space of dielectric strength; after that the recovery of dielectric strength is much slower. Curves *A*, *B*, and *C* indicate that the immediately recovered dielectric strength is independent of the arc length. As shown by curve *C*, the slope was found to decrease with an increase of arc length. Curve *D*, however, indicates that for heavier currents there is an extremely low value of immediately recovered dielectric strength, and an extremely small slope of the characteristic for the first few hundred microseconds.

Earlier tests made by Kehoe indicate that the arc following a fault in an a-c. network cable will always be extinguished at 220 volts r. m. s. At 1,000 volts r. m. s., currents up to 500 amperes, and at 2,000 volts r. m. s., currents up to 100 amperes were also successfully interrupted by the arc. Although the tests at higher voltages were not conclusive, it appeared certain that at 220 volts the arc would be extinguished under all circuit conditions. These, and the results of other similar tests, are entirely compatible with the earlier data on arc reignition characteristics, such as curves *A*, *B*, and *C* of Fig. 12.

The more recent results indicated by curve *D*, and which should be more directly applicable to cable-fault arcs, are not compatible with these results. According to curve *D*, arcs with currents exceeding 1,200 amperes would not be extinguished with more than 125 volts or 130 volts r. m. s. in a low-power-factor circuit. We are then driven to the conclusion that in a-c. cable-fault arcs there must exist additional deionizing agents which are not active in ordinary short arcs between metal electrodes.

These additional deionizing agents must come from the insulation used in cables, and the authors believe that it comes from the intense blasts of gas directed to the arc from the adjacent decomposing insulation. This turbulent inpouring of fresh, relatively cool, un-ionized gas from the decomposing insulation may well cause the extinction of the arc in circuits of voltage higher than otherwise would be possible. Gases which are inflammable and under certain circumstances even may constitute an explosion hazard, are probably necessary in the functioning of low-voltage a-c. networks.

Tests on Arcs in Cables

Further substantiation of the important part insulation plays in the extinction of the arc, and an indication of the persistency of the arc when not subjected to the influence of insulation, was shown in a number of copper-to-copper short circuits made in short lengths of oil-impregnated paper-insulated cable. The cable used was 600-volt, three-conductor, 500,000-cir. mil lead-covered cable manufactured by the Habirshaw Cable Company. The arcs were started in several different ways, and were made in a 550-volt r. m. s. 60-cycle circuit in which the current was limited only by

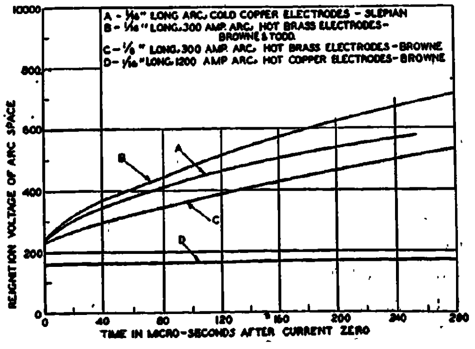

Fig. 12. Test curves of arc reignition characteristics

From "Arcs in Low-Voltage A-C. Networks," (No. 31-84) presented at the A.I.E.E. Middle Eastern District meeting, Pittsburgh, Pa., March 11-13, 1931.

the reactive impedance of the transformers and cables. Currents varied from 3,000 to 10,000 amperes. In some of these tests the short circuit was made near the end of the cable opposite the power supply, and in others near the middle of the cable section, power being supplied from both ends to eliminate the strong magnetic blowout effect that is present with the first method of short-circuiting.

In general it was found that when the arc was closely bounded by insulation it would be extinguished in from one to fifteen half cycles. Occasionally, however, the arc would persist, and it was then found that placing resistance in shunt with the arc having a value as low as one ohm, had no influence on the extinction of the arc. In those tests where the insulation had been carefully cleaned away about 6 in. or more from the arc, the arc would then persist, and the arc voltage was about 350 volts, or three or four times as large as when the arc was bounded closely by insulation. This value is very much too high for an arc drawn in air and unexposed to any gas blasts. The only conclusion which can be reached is that it was caused by the decomposition of the insulation.

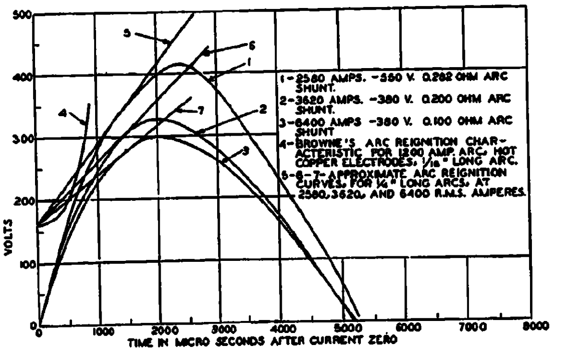

Fig. 13. Calculated circuit reignition characteristics are given in curves 1, 2, and 3

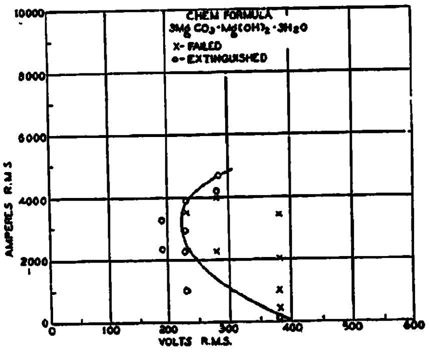

Fig. 14. Arc extinguishing properties of basic magnesium carbonate

Tests on Arcs Between Copper Plates

Definite confirmation of the importance of the decomposing insulation in extinguishing arcs, as well as quantitative results on both organic and inorganic insulation at heavy currents were obtained in a group of short-circuit tests made between a pair of copper plates. These were ¼ in. thick and 4 in. by 27 in. in area, spaced about ¼ in. apart. To keep the gas pressure between the plates low, ½-in. holes, spaced 1.41 in. between centers, were punched in the plates.

Tests were first made using only an air-gap between the plates, and values were determined for resistance which when in shunt with the arc would just cause it to go out. With these values the circuit reignition characteristics should be just tangent to the arc reignition characteristic. Three calculated "circuit reignition characteristics," or tendency of the circuit to build up voltage across the arc space are shown in Fig. 13, in which curve *D* from Fig. 12 is redrawn, and three probable arc reignition characteristics for the larger currents and spacing are indicated by curves from the 160-volt point on the voltage axis tangent to the various circuit reignition characteristics.

Arc potentials in these tests were found to vary from 40 to 100 volts, and it was shown decisively that the simple short arc between copper electrodes free from insulation is inadequate to meet the fault-clearing requirements of low-voltage a-c. networks.

Further tests were made with the same electrode arrangement but with oil-filled paper clamped between the copper plates, the fuse for starting the arc being passed through a ⅛-in. hole in the paper. At 550 volts the arc was extinguished for all values of current tried, up to 11,000 amperes. Similar results were obtained as the voltage was increased to 750, although at 1,150 volts the arc persisted. The arc potential was found to vary from 300 volts at low currents to 600 volts for high currents. Increasing the size of the hole to ⅜ in. caused the arc to persist at 550 volts, and the arc voltage was only about 200 volts. Tests in which the paper was impregnated with vaseline and with glycerine gave results practically the same as for the oiled paper, and the important part played by the insulation in the extinction of cable arcs was again affirmed.

Preliminary tests were then made using inorganic insulation which would give off incombustible gases such as water or carbon dioxide. The various materials in the form of powder were packed between the copper plates, and tests were then made as before. The arc was permitted to make as large a hole as it would in the closely packed, powdered material.

The results shown in Fig. 14 for basic magnesium carbonate are typical of the relation between the current and the voltage that can be interrupted by a given length of arc. As the current is increased from small values, the volts which can be interrupted, decrease, reach a minimum, and then increase again. This relation is rather to be expected if it is recalled that for very large currents the gas blast will be very intense, and that for very small currents the arc will be particularly sensitive to deionizing influences.

If, now, the voltage of the circuit is kept constant and only the circuit reignition characteristic is altered, similar results are obtained. Below a certain "speed" of circuit all currents are interrupted, whereas for higher "speeds" there will be an intermediate range of current for which the arc will persist.

This is illustrated in Fig. 15 which shows the results of tests using gypsum powder. All these tests were at 550 volts, with varying values of resistance shunting the arc to give different circuit reignition characteristics. For shunting resistances of less than 16 ohms, the arc interrupted all values of current; but for resistance greater than 16 ohms, there would be an intermediate range of current for which the arc would persist.

Because it so happens that most of the data for the different powders were obtained at 550 volts with varying resistance shunts, their efficacy may be compared by plotting in one figure several curves similar to that of Fig. 15. This has been done in Fig. 16. No curve is given for boric acid, as the arc interrupted all values of current even when unshunted, except for one test which did not repeat itself. The curve for gypsum is taken from Fig. 15, and consists of the boundary of the region of arc persistency. The other curves were obtained in a similar manner.

From all these data it is concluded that boric acid made the best arc-extinguishing powder, being as good as oiled paper over the range of these tests. The next, although considerably inferior, is gypsum. Then far inferior, though better than plain air, are the rest of the materials tried.

ARC-EXTINGUISHING SUBSTANCES

From these tests it will be noticed that some requirement other than the amount of gas generated for a given volume, or for a given energy input from the arc, must be taken into account. This other factor probably relates to the state of the surface of the bounding material just after the moment of arc extinction. Even though the arc will not reignite in the arc space itself, the surface of the bounding material must be able to withstand the voltage without breaking down. Organic insulation in general seems to meet this requirement, as the surface remains clean and is of good insulating quality.

Ammonium carbonate, however, melts below the temperature at which rapid decomposition takes place, and the surface of the material which is left after a half cycle of arcing undoubtedly consists of a molten film of the ammonium carbonate which is highly conducting. A considerable current flows in the molten surface film, and the resultant tearing of this film while carrying current will restart the arc. Although boric acid also has its melting point below that at which rapid decomposition takes place, the electric resistivity of the molten boric acid is very high. The current will be so small that the power will be insufficient to keep the boric acid film hot, and it will recongeal, thus permanently opening the circuit.

While organic insulation in general has the property of being left with a surface of good dielectric quality after exposure to the arc, it may not have this property after it has been subjected to a moderately high temperature, so that it is more or less charred before the arc begins to act upon it. Insulation which has become charred for any reason is ineffective in causing the extinction of the arc, because it has lost its more volatile constituents and because after exposure to the arc, the surface which is left is almost entirely free carbon and a good conductor while hot. With normal organic insulation, the rapid evolution of gas seems to scour away the surface and keep it clean of carbonaceous residues; but the charred insulation has lost this property.

W. R. ROSS
Associate A.I.E.E.

Both of the
Philadelphia (Pa.)
Electric Company

Because several of its basic features differ quite radically from other distribution networks, the engineering plan of the Philadelphia a-c. network is outlined and five years' operating experience is summarized.

THIS SYSTEM at present comprises 24 sectionalized primary loop feeders supplying three separate fused secondary networks areas totaling 1.26 sq. mi. The total 1930 peak load of the central business district of Philadelphia amounted to 72,820 kva., of which the a-c. network system carried 27,600 kva. and the remaining d-c. system 6,000 kw. The remaining 39,220 kva. is fed generally in large blocks at 2.3 or 13.2 kv. Supply for the whole area comes principally through four substations which in turn are fed from two steam-electric generating stations located about 1½ mi. away.

Each network area is fed by four primary loop feeders from each of two substations. These feeders are composed of three-conductor, 350,000-cir. mil paper-insulated lead-covered cable now operating at 2.3 kv., three-wire, two-phase, but designed for ultimate three-phase operation at 13.2 kv. Each feeder is routed through widely separated parts of its network area, interlaced with other feeders, and carried through several intersections to return finally to the substation of its origin. The several "unit-sections" of each primary loop are joined through 400-ampere 15-kv. subway-type oil circuit breakers subject to the control of the balanced pilot-wire protection scheme. For a standard 2-OCO-duty cycle at 2.3 kv. these breakers have a rupturing capacity of 30,000 amperes.

Network distribution transformers are all 100-kva. subway-type units of standard impedance. Most of them are constructed with the high-voltage winding in six sections, connected in parallel for present 2.3-kv. operation and permitting series connection for possible future operation at 13.2 kv. All of these transformers are installed in manholes usually four in a group together with one oil circuit breaker, two pilot cable junction boxes, and four low-voltage sectionalizing boxes. Barrier walls are not used in these manholes, but all (except control) cables are fireproofed.

The secondary a-c. network system is a grid of two-phase, five-wire 115-230-volt mains. This grid is fed from the primary loops through transformer banks placed at each main street intersection. To provide automatic isolation in cases of trouble the secondary mains and transformer leads are equipped with copper link fuses. These fuses are installed in five-way, single-polarity sectionalizing boxes to which the four secondary mains and the transformer leads are connected. Fuse capacities used are 1,250 amperes for mains and 1,500 amperes for transformer leads.

In the secondary network 350,000-cir. mil, 600-volt, paper-insulated, lead-covered cables are used. Single-conductor cables from the fused sectionalizing boxes may be spliced to single- or multiple-conductor mains. In many instances the three-conductor cables of the former d-c. network were used for one phase and two single-conductor cables installed to complete the system of two-phase mains. Present practise is to install single-conductor cable for the phase wires and a 2/0 bare neutral wire.

Both lighting and power loads are fed from the same set of secondary mains. No auto-transformers are required on the secondary network because the system conforms to accepted voltage standards for both light and power. Thus all parts of the system may be paralleled at will. It is of interest, too, to note that two-phase motors up to 40 hp. are taken on any part of the network, when well established, without requiring current-limiting devices for starting.

OPERATING EXPERIENCES

In general, five years' operating results with the Philadelphia network system have been satisfactory. Some of the more important operating experiences are outlined briefly in the following paragraphs.

1. In one case, trouble in a generating station cut off the power supply to a pair of substations feeding one of the network areas, dropping a 5,000-kva. load. Service was restored promptly, however, by resorting to the use of interstation tie lines. This enabled one of the dropped substations to pick up the whole area load during the emergency period.

2. In the second of two instances where system disturbances affected network areas, no service interruption occurred. In this case the 132-kv. transmission feeders to one of a pair of network-area substations were lost successively, dropping the entire area load of about 6,000 kva. on the second substation. This second substation thus carried for the emergency period all of its own load, the whole network-area load, and (through feedback) several important radial feeders from the first substation.

Careful scrutiny of this diagram will reveal many details supplementing the accompanying text

Table I—Data Pertaining to the Philadelphia A-C. Network System—1930 Peak

		Delaware north	Delaware south	Schuylkill south	Totals December 1930
1.	Area in square miles operating network	0.413	0.467	0.376	1.256
2.	Maximum demand in kva. (network only)	8,023	9,897	9,682	27,602
3.	Number primary loop feeders	8	8	8	24
4.	Total normal capacity of loop feeders	10,620 kva.	9,600 kva.	12,320 kva.	32,540 kva.
5.	Average normal load per loop feeder	1,003 kva.	1,237 kva.	1,210 kva.	1,150 kva.
6.	Total length of loop feeder cable	70,400 ft.	99,800 ft.	92,400 ft.	262,600 ft.
7.	Average length per loop feeder	8,800 ft.	12,475 ft.	11,550 ft.	
8.	Total length of loop feeder cable between substation and first transformer bank	17,160 ft.	36,698 ft.	30,240 ft.	84,098 ft.
9.	Total length of loop feeder cable between substation and boundary of network area		21,292 ft.	6,805 ft.	28,097 ft.
10.	Number of unit sections on loops	57	70	72	199
11.	Average loop section length in feet	1,230 ft.	1,430 ft.	1,280 ft.	1,320 ft.
12.	Number of primary oil circuit breakers	49	62	64	175
13.	Installed transformer capacity kva	12,500	13,600	15,400	41,500
14.	Number of transformers (100 kva.)	125	136	154	415
15.	Number of transformer manholes	41	54	56	151
16.	Ratio normal loop feeder capacity to transformer capacity	85%	71%	80%	78%
17.	Ratio maximum coincident feeder demand to transformer capacity	64%	73%	63%	66%

3. Some 22 cable failures and three transformer failures have been isolated successfully without interruption to service in any unit-section other than that directly affected, and without impairing service to any customer. Cable failures have averaged one per 3½ unit-sections per year, or 12 per 100 mi. of operating cable per year, the relatively high average being due largely to external mechanical injury. Transformer failures were caused by water leakage and consequent insulation breakdown.

4. The first consignment of oil circuit breakers caused trouble by tripping out from vibration, a trouble relieved by proper mechanical corrections. Excepting one other instance—a failure caused by water leakage—these breakers have given satisfactory service and have required only a minimum of maintenance.

5. The operation of fuses in these network areas has demonstrated that secondary faults are quickly and selectively isolated, and that the sizes used are satisfactory. There have been no cases of fuses blowing when a fault did not exist in that particular section. When fuses have not blown, faults have cleared themselves; in two cases they burned clear within a few inches of the point of origin.

6. In the pilot-wire relay system field inspections to date have disclosed three cases of failure in the four-conductor (No. 4) rubber-insulated, lead-covered cable. Also two cases of incorrect cable connections and one defective current transformer were discovered. However, none of these six irregularities caused circuit-breaker operation.

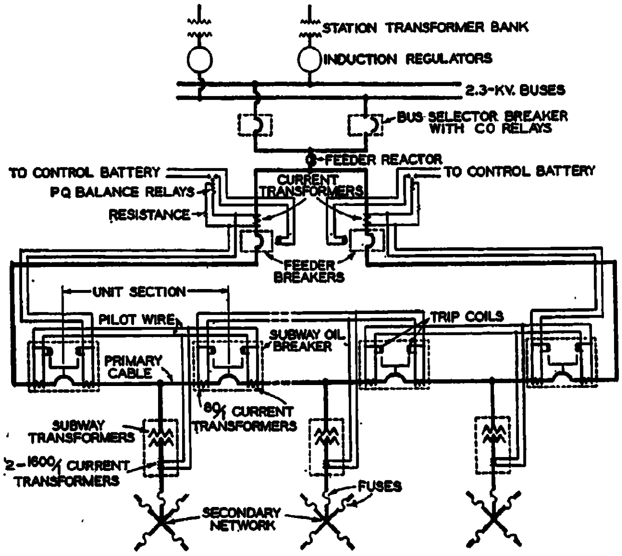

Fig. 2. (Above) Single-line diagram of pilot-wire relay protection system for a typical primary loop

It may be noted that only one transformer bank and associated cable is isolated in the event of a fault on the primary loop feeder

An inspection is made every three months by a group of five men to determine the condition of all equipment associated with the network. It is expected that with further operating experience the frequency of inspection may be reduced safely. In detail the inspections consist of:

1. Testing transformers, oil circuit breakers, and fuse boxes for water-tightness. The work involved in making equipment water-tight accounts for most of the inspection time.

2. Testing the entire pilot-wire relay system for grounds, open circuits, and short circuits.

3. Checking sensitivity of trip coils and operating mechanisms.

4. Looking for blown fuses and open secondary cable mains in the sectionalizing boxes.

5. Minor repairs and adjustments to all equipment as required.

Open breakers on the primary loop circuits are checked (1) by recording the hourly ammeter reading on each loop feeder, (2) by twice each week opening alternately the loop feeder ends, and (3) checking the approximate total currents under these test conditions. The current readings on each loop-end often indicate an open section and its approximate location.

CONSISTENCY IN A TEN-YEAR PLAN

Since the first Philadelphia a-c. network area was established in 1926 as an integral part of a ten-year program of changing the downtown business district from d-c. to a-c. distribution, the system plan initially adopted has been followed without fundamental change, and has proved amply flexible to meet changing load conditions. With the aid of an a-c. "system calculating board" the proposed system was laid out in detail to meet the general requirements:

1. That the network system as a whole should have sufficient spare capacity to insure against overloading any equipment during periods of unit-section or transformer outage; and

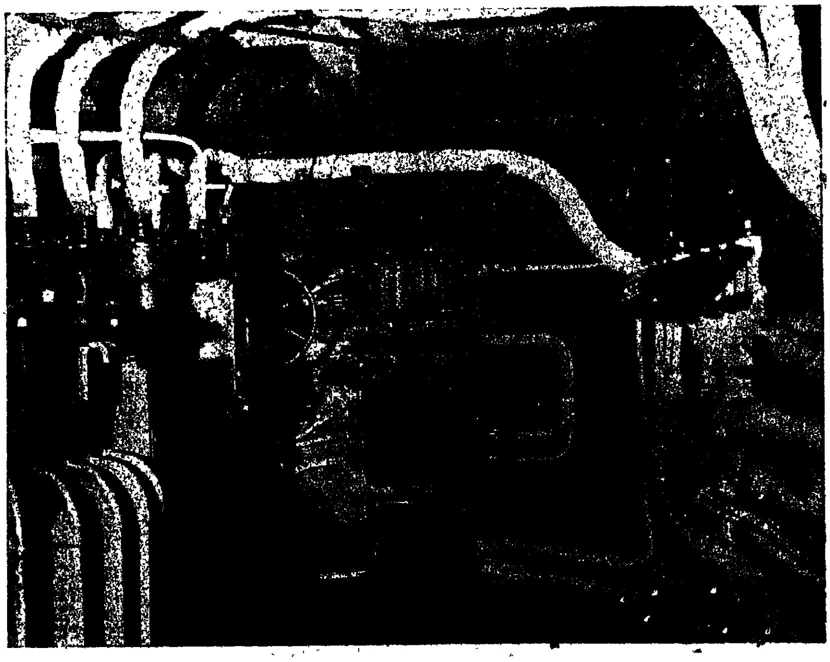

Fig. 3. (Right) Typical transformer manhole showing—left to right—transformer, oil circuit breaker, pilot cable junction boxes, and secondary sectionalizing boxes

Most manholes are 15 x 9 ft. in plan with 8-ft. headroom, and are located in the highway beneath the sidewalk. Two openings are covered by removable slabs, one of which has an open-grating lid and two openings for ventilating ducts which ducts extend from street surface to bottom of the manhole at each end

2. That adequate network voltage should be maintained under all conditions, including short-time (30 min.) loss of one of the two substations supplying any given area.

Both of these requirements have been proved in practical operation.

Synchronous Machine Constants

COMPANION papers "Calculation of Synchronous Machine Constants" by L. A. Kilgore and "Determination of Synchronous Machine Constants by Test" by S. H. Wright (see footnote) both of the Westinghouse Electric & Manufacturing Company, have been presented before the A.I.E.E. Until recently the theory of synchronous machines has required relatively few constants; a single value of reactance, usually called armature leakage, has been used to calculate the initial short-circuit current, and standard decrement curves have been applied to determine the rate of current decay. However, the need for greater accuracy in short-circuit and stability calculations has brought into quite general use the new theory involving symmetrical components. The various reactances and time constants affecting transient characteristics must be known in applying the new theory, and consequently there is a real demand for knowledge of these constants.

The paper by Mr. Kilgore presents a method of calculation for all the more important constants, except the subtransient time constant. The principle of superposition is applied to resolve the reactance accurately into components which can more readily be calculated. The induced current in the field and additional damping circuits are accounted for in a simple manner by applying the constant interlinkage theorem. Comparisons of test and calculated values are given, and formulas for the constants of both salient-pole and turbine generators are derived in the appendix.

Every designer of large synchronous machines has to meet this problem of calculating the constants and those who use the constants in other applications also are interested in knowing how accurately they can be calculated. Their application rather than their calculation has been the subject of most of the previously published information.

The paper by Mr. Wright, discusses the results of an investigation including extensive tests of the constants of various synchronous machines representative of those found in modern hydroelectric or steam-electric power systems. Although there is as yet no accepted set of definitions which standardize the meaning of these reactance constants, time constants, and resistances, they are discussed from a practical standpoint and methods for their determination from tests are described. Also are given details of the application of these methods to an extensive group of tests actually made.

These tests show the importance of such factors as saturation in the analysis of machines operating under short-circuit conditions. Saturation was found to be particularly important for turbine-generators, due largely to the inherently low reactance and therefore high short-circuit current of this type of machine. As a result, variations in some of the constants were found and are presented in the paper. The author advocates that unless otherwise qualified, reactances and time constants should be based on what are termed "saturated" values. Based upon the extensive tests performed, tables are given to show the values of the constants for various types of machines. These afford means of estimating the characteristic constants of the various synchronous machines that are found on the power systems of today.

Field Transients in Magnetic Systems

MAGNETIC CIRCUITS generally are composed of magnetically different materials which have different characteristics such as magnetization curves, electrical conductivities, and thermal properties. The most important distinction, however, lies in the use of laminated and solid iron parts, both of which show extreme behavior in the case of transient phenomena. When any change of the associated magnetic field takes place, eddy currents are produced in the iron, and these eddy currents produce a reacting magnetic field. This condition delays the rate of change of the resultant field. In the case of laminated iron parts, the very structure of the system limits the amount of eddy current to a negligible value. However, the delay of the growth of the magnetic field in solid iron parts is one of the most important factors in the operation of many types of electrical equipment.

Previous solutions of this general problem have been based upon special assumptions which do not take

accurate account of the interlinkage of eddy current and exciting current. Ernst Weber in an A.I.E.E. paper (see footnote) presents a complete mathematical solution of suddenly applying a d-c. voltage to an electromagnetic circuit composed of an electric coil with a partly laminated and partly solid iron core containing an air-gap. Starting from Maxwell's field equations for the eddy current and the magnetic field in the iron core, the solution of the time conditions is reached with the aid of Heaviside's operational calculus. The result is expressed by means of a time constant of the magnetic field, composed of the time constant of the electric circuit and a fraction of a newly defined time constant due to the eddy currents in the iron part. The influence of the various dimensions of the solid iron part on the rate of change of the magnetic field is shown quantitatively. The results of the method described are illustrated by a numerical example.

The method is of considerable importance in a number of practical applications, such as the operation of relays; in the pulling into step of synchronous motors; in the short-circuiting of and quick-response excitation of large alternators; in production schedules depending upon changes in speed of large industrial motors; in the proper performance of all motors in the field of transportation; and in all magnetic-electric systems where regulation is influenced by the magnetic inertia. This problem is not only electrically, but economically and mechanically, important since the design of such equipment depends upon the relative amount of solid iron which may be used in extreme cases without disturbing the required characteristics of operation.

Transient Oscillations in Distributed Circuits

OSCILLATIONS in transformer and other distributed windings have been subject to analysis both by test and calculation; the mathematical investigation of such oscillations is extended by L. V. Bewley (see footnote). In this paper, the nature of the initial, transient, and final distributions of potential are mathematically analyzed and discussed, showing the effects of the following:

1. Losses
2. Circuit constants
3. Neutral impedances
4. Applied wave shape
5. Available methods for controlling distribution

The losses in a transformer circuit during a high frequency transient are due to series resistance in the winding (including skin effect) and dielectric losses and leakage currents from the winding to ground and between points at different potentials on the winding. These losses have a four-fold effect on the character of the oscillations: (1) the amplitudes of the harmonic oscillations are decreased; (2) the frequencies of the harmonic oscillations are slowed down; (3) decrement factors are introduced; and (4) the final distribution is not linear. It is theoretically possible to choose such losses that all oscillations vanish.

In analyzing the effects of circuit constants, most distributed circuits may be classified under four ideal combinations: (1) self-inductance and ground capacitance (the transmission line); (2) self-inductance, series capacitance, and ground capacitance; (3) self- and mutual inductance, and ground capacitance; and (4) self-inductance and mutual inductance, series capacitance and ground capacitance (the transformer). The effects of these different combinations of circuit constants are described by equations and graphs in the complete paper. It is shown that they may be discussed from three different points of view: (1) fixed distribution plus harmonic standing waves; (2) fixed distribution plus harmonic traveling waves; and (3) simple traveling wave plus distortion terms. Complete sets of curves for the initial and final distributions are given.

A rigorous mathematical treatment for any generalized neutral impedance is not attempted, but two approximate methods of analysis are given. In the first method, the neutral voltage is determined by solving the approximate external equivalent circuit of a transformer, and, using this voltage as an applied wave; the corresponding distribution then is found and added to the distribution due to the wave at the line terminal and with the neutral grounded. This method is illustrated for a capacitance in the neutral. In the second method, the circuit consisting of self-inductance, ground capacitance, and series capacitance is used to represent the transformer, and the solution for the neutral voltage obtained by means of the Heaviside operational calculus. This latter method gives fairly good results for the neutral voltage, but only a rough approximation for the internal distribution.

The solutions are given for the following representative applied wave shapes, and the general method of analysis is specified: (1) infinite rectangular wave; (2) finite rectangular wave; (3) uniformly rising front; (4) typical lightning wave; (5) damped oscillation; and (6) sustained oscillation. The solution for each of these cases is illustrated either by graphs or cathode ray oscillograms, or both.

The control of the transient distribution is discussed with respect to: (1) maintenance of constant neutral

---

Abstracted from "Transient Oscillations in Distributed Circuits, with Special Reference to Transformer Windings" (No. 31-96) by L. V. Bewley, presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

conditions, and (2) control of the oscillations by shunt or series capacitances or combinations of both, by ground capacitance, and by losses. It is shown that while the addition of ground capacitance increases the amplitudes of the space harmonics, it slows the natural frequency of oscillation, and therefore may prevent the occurrence of abnormal voltage to ground before the applied terminal wave has disappeared. However, it increases the gradients along the winding, and therefore does not offer the ideal solution that their elimination provides. Stress is placed on the control of oscillations by the use of losses, particularly by shunt resistance with an exaggerated negative characteristic; and the possibility of a combined lightning arrester and tied-in shunt resistor for controlling the distribution is pointed out. There also is included in the paper a short historical sketch on this phase of transformer investigations, and a short bibliography.

Non-Linear Circuits for Relay Applications

Study and analysis of non-linear circuits reveal characteristics which mark them as capable of being adapted to a variety of special uses. A simple series circuit of this type is especially well adapted for relay applications, and obviates some of the undesirable features of mechanical relays.

By
C. G. SUITS

General Elec. Co.
Schenectady, N. Y.

No PRACTICAL problems lend themselves to solution by available mathematical tools as readily as do linear electrical circuits. In non-linear circuits, however, wherein the magnitude of the different elements of inductance, capacitance, or resistance, become functions of the current or other variables, the analytical problem is complicated greatly. Mathematical impedimenta need not intimidate the experimental approach, however, for many of the non-linear circuits may be studied in this manner with the simplicity characteristic of the more familiar circuits. In this connection it is probable that a lack of that potent aid to research—analysis—accounts in some degree for the present elementary state of development of this type of circuit.

Many so-called linear circuits containing ferromagnetic core material possess linear characteristics over their normal operating ranges, but do not even approximate linear operation during abnormal conditions. For this reason these supposedly linear circuits sometimes behave in a manner regarded as anomalous, when in reality such behavior is related directly to the fundamental *non-linear* nature of the circuits. Thus various types of instability in power circuits incorporating capacitance probably can be analyzed in terms of elementary non-linear circuits. A careful study and analysis of various circuits will reveal many applications not readily apparent. One application of this character consists in the use of a simple series non-linear circuit in conjunction with apparatus already available for a non-mechanical relay having practically ideal characteristics.

The voltage-current characteristic for a series non-linear circuit consisting of resistance, capacitance, and an iron-core inductance, may be seen in Fig. 1. The similarity between this characteristic and the characteristic for an ideal relay is evident at a glance. As may be seen from the curve, this circuit is "voltage sensitive," that is, at the critical voltage a large current rise may be observed in response to a small change in voltage. Thus at or near this critical point, a change in voltage of only 0.01 per cent may result in a 100 per cent increase in current.

An oscillographic study of the circuit of Fig. 1 reveals that the low-current region *A* is associated with the magnetically unsaturated region, or more properly the hysteresis region of the iron-core reactor, while in region *C* the current has risen to such values that saturation has taken place. Region *B*, or the critical part of the voltage-current curve, corresponds to that portion of the magnetization characteristic of the core material loosely referred to as the "knee," and in this region the instantaneous current rise is such that the instantaneous capacitance and inductance voltages are equal and opposite during some portions of the voltage

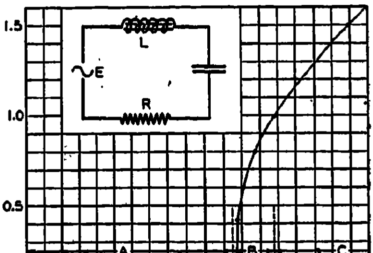

Fig. 1. Voltage-current characteristic for a series circuit containing as its non-linear element an iron-core reactor

---

Based upon "Studies in Non-Linear Circuits" (No. 31-37) presented at the A.I.E.E. winter convention, New York, Jan. 26-30, 1931.

cycle. In this limited region of resonance the peak value of current is limited only by resistance, and thus may be calculated from the d-c. resistance of the circuit and the corresponding instantaneous value of applied voltage.[8] This condition is illustrated by the oscillogram shown in Fig. 2. Here the cyclic period of resonance occurs during the interval indicated by arrows, and during this period also the current is at its peak value. This quasi-resonant state has been called non-linear resonance to distinguish it from linear resonance from which it differs in important respects. Non-linear resonance is analogous to linear resonance in that the current is resistance-limited, and that the sum of the reactance voltages is zero; it differs from ordinary resonance phenomena, however, in that the period during which the resonance condition

$$-l\frac{l}{C}\int i\,dt = L\frac{di}{dt} = K\frac{d\Phi}{di}\,\frac{di}{dt}$$

is satisfied, occupies but a small portion of each steady-state cycle.

APPLICATION TO A-C. RELAYS

A relay must possess in general two characteristic properties: (1) a non-linear actuating characteristic, and (2) capability of power amplification, which means that the ratio of controlled to consumed power must be high. The voltage-current characteristics of a series non-linear circuit make it admirably well adapted to fulfilling the first mentioned requirement. The second requirement may be obtained by combining this circuit with the saturable core reactor as shown in Fig. 3. The saturable core reactor (A.I.E.E. JOURNAL, Oct. 1924, p. 958-66) is essentially a special type of reactor having a-c. load windings and d-c. control windings so arranged that no power is transferred between the load and control circuits. In the arrangement shown in Fig. 3 the voltage across the capacitance in the resonant circuit is used to actuate the saturating reactor which in turn controls a load through its a-c. circuit.

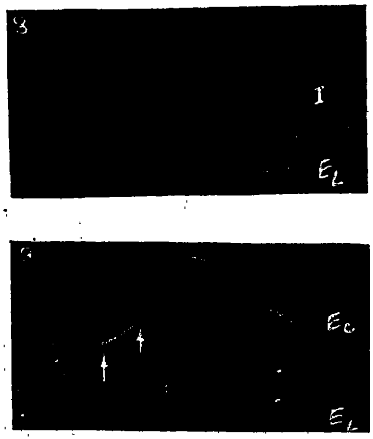

Fig. 2. Typical oscillograms showing voltage and current relations for range "B" of Fig. 1. Arrows denote range of non-linear resonance

I —current
E_L—inductance voltage
E_C—condenser voltage

Voltage-current characteristics for different parts of this relay arrangement also are shown in Fig. 3. Overall operating characteristics of the device are indicated in the curve I_3, which is a close approximation to the characteristics of an ideal relay. Curves are shown for two values of load resistance (R_2). From these two curves it is quite obvious that the ratio of "on" to "off" load current may be made as large as desired, it being a function of the design of the saturating reactor, and governed by the same considerations as in all circuits where this device is used.

Of some importance in this application is the amount of power which may be controlled in a relay of this type. For a saturable core reactor the power amplification factor is a function of the maximum and minimum values of impedance required, which are related in turn to the "on" and "off" load current. Theoretically, the power amplification of a reactor of this type is quite unlimited but practically a factor of 1,000 for an incandescent lamp load has not been exceeded to date. This present limit can be exceeded quite readily, however, by cascading the saturable reactors. Since there is no limit to the number of reactors which may be cascaded, accordingly there is no limit to the power amplification that may be obtained. It may be interesting to note that in an experimental set-up a power amplification of 10,000 is obtainable in only two stages, and with comparatively inefficient equipment.

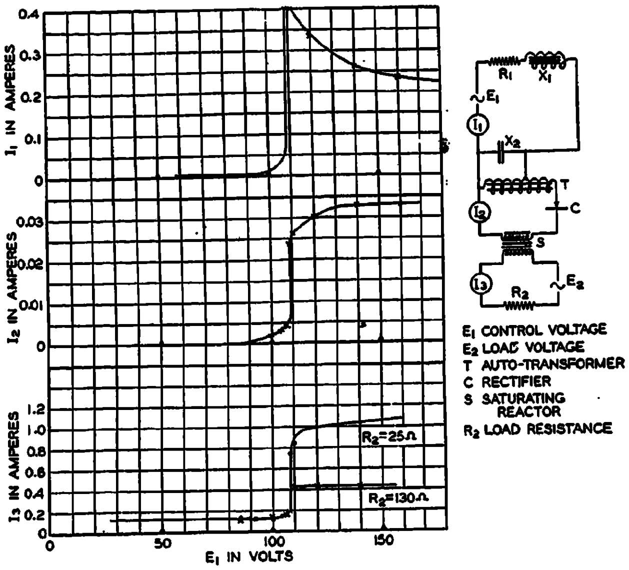

Fig. 3. A-c. relay made up of a series non-linear circuit and a saturable-core reactor with voltage-current curves for different circuit branches

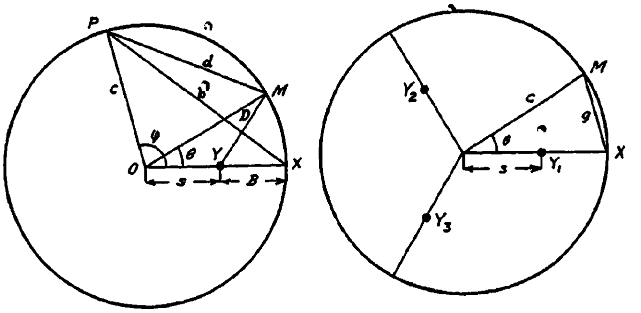
The sensitivity of resonant relays is limited by the characteristics of the resonant circuit and of the saturable reactor circuit. The most sensitive relay action is obtained when only a small amount of power is taken from the resonant circuit and in practical relays a 1 per cent change in voltage has been found sufficient to determine the "on" or "off" condition. Constancy of the control circuit frequency is another factor influencing to a certain extent the relay sensitivity. With a supply frequency of 60 cycles, however, variations in relay operating voltage are only about 1 per cent per cycle change in frequency. Means are available for obtaining still greater sensitivity, but up to the present time no application has required it.

Proximity Effect in Cable Sheaths

Formulas supplementing those previously published and making it possible to calculate the losses in cable sheaths simply and accurately are presented herewith. These cover a wid range of cases.

By
H. B. DWIGHT
Fellow A.I.E.E.

Massachusetts Institute of Technology, Cambridge



Figs. 1 and 2. Thin tube with enclosed filament (left) and three-phase cable with sheath (right)

LEAD SHEATHS of underground cables, being conductors two or three inches in width, usually will have noticeable circulating currents flowing in them due to the proximity of electric power currents. The calculation of the circulating currents and their losses is called a proximity effect calculation, and the result takes the form of a power series.

The problems encountered deal with current density, energy loss, and voltage drop. Certain of these are discussed in "Losses in Grounded Sheaths of Single-Conductor Cables," by H. B. Dwight, *Electric Journal*, Feb. 1924, p. 62. Methods are now available for applying these calculations to a wider number of cases and with increased accuracy.

Considering a very thin tube enclosing a filament as in Fig. 1, the current in the sheath is

$$i_{(\theta)} = -\frac{I}{\pi c t}\sum_{n=1}^{\infty}\frac{s^n}{c^n}\,\frac{l^4 + j\,l^2 n}{l^4 + n^2}\cos n\,\theta \qquad (1)$$

where

I = current in filament at Y

c = mean radius of tube in cm.

t = thickness of tube in cm.

s = distance in cm. from center of sheath to centers of the copper conductors

$$l^2 = \frac{\omega\, 2\,\pi\, c\, t}{\rho_s}$$

$\omega = 2\,\pi\, f$

f = frequency in cycles per sec.

ρ_s = resistivity of the tube in abohms per cm. cube

If there are currents in more than one location within the sheath, each produces its own sheath current independent of the others, and the total sheath current is obtained by addition. The result of distributed currents is given by integration.

ENERGY LOSS CALCULATIONS

The loss in the sheath of a three-phase cable is of importance with cables of large size. Referring to Fig. 2 the loss in the open-circuited sheath is given by the following expression, which was published by F. W. Carter, as eq. 19 in the *Proc. of the Cambridge Phil. Soc.*, V. XXIII, 1927, p. 905.

$$\frac{\text{Loss in lead sheath}}{\text{Loss in three copper conductors at 0 freq.}} = \frac{2\,a^2}{c\,t}\,\frac{\rho_s}{\rho_c}\sum_{n=1}^{\infty}\frac{s^{2n}}{c^{2n}}\left(\frac{l^4}{l^4 + n^2}\right)\sin^2\left(\frac{n\,\pi}{3}\right) \qquad (2)$$

where

a = radius in cm. of a solid copper wire of the same resistance as the stranded copper conductor

ρ_c = resistivity of copper

Calculations based on these formulas for three-conductor three-phase cables with open-circuited sheaths indicate that the sheath loss with a typical cable of 500,000 cir. mils per conductor is 5 per cent of the loss in the three copper conductors at 0 freq., and in a typical large cable of 1,000,000 cir. mils per conductor the sheath loss is 15 per cent of that in the three conductors.

The loss in short-circuited non-magnetic sheaths in a

From "Proximity Effect in Cable Sheaths" (No. 31-72) presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931.

single-phase circuit is given by eq. 28 of the *Electric Journal* article previously referred to. However, this equation can be improved by making it more rapidly convergent for wide spacings between the cables. This is done by a slight change in the calculation, making the initial terms the same as in the usual impedance formula.

Using the notation of the present article let

$$P = \frac{-j\ \omega \operatorname{logn} \dfrac{s}{c}}{j\ \omega\ 2 \operatorname{logn} \dfrac{s}{c} + \dfrac{\rho_s}{2\pi c t}} \tag{3}$$

$$F_n = j\, l^2 (1 + 2P) \frac{c^n}{n\, s^n} \tag{4}$$

$$B = j\, l^2 \left[-2A \operatorname{logn} \frac{s}{c} + \sum_{k=1}^{\infty} \frac{c^k}{k\, s^k} F_k \right] \tag{5}$$

$$G_n = j\, l^2 \left[2A \frac{c^n}{n\, s^n} - \frac{F_n}{n} + \frac{c^n}{n\, s^n} \sum_{k=1}^{\infty} \frac{(n+k-1)\,!}{(n-1)\,!\,k\,!} \frac{c^k}{s^k} F_k \right] \tag{6}$$

n and k denote integers.

In the equations for B and G_n, $A = 0$. For C and H_n use the formulas for B and G_n respectively, except change A to B and F to G. Similarly for D and I_n, change A to C and F to H, and so on.

$$L = P + B + C + \ldots \tag{7}$$

$$M_n = F_n + G_n + H_n + \ldots \tag{8}$$

$$\frac{\text{Loss in sheath}}{\text{Loss in conductor at zero frequency}} = \frac{a^2}{c\,t} \frac{\rho_s}{\rho_c} \left[2\,|L|^2 + \sum_{n=1}^{\infty} |M_n|^2 \right] \tag{9}$$

$|L|^2$ is the square of the absolute value of L.

An approximate formula for this loss ratio is

$$\frac{2a^2}{c\,t} \frac{\rho_s}{\rho_c} |P|^2 \tag{10}$$

A typical example calculated for a 60-cycle, single-phase circuit with 2,000,000 cir. mil single-conductor cables indicated a sheath loss of 49 per cent of the loss in the conductor at 0 frequency, based on eq. 9, while the approximate formula eq. 10 indicated a loss of 41 per cent. This latter value is the same as would have been obtained using the well-known approximate formula

$$\text{Effective resistance} = R_c + \frac{R_s X_m^2}{R_s^2 + X_m^2} \tag{11}$$

When three single-conductor cables with short-circuited lead sheaths lie in a plane and carry balanced three-phase current, the losses in the two outer sheaths are not the same. The difference is great enough to justify adding a formula for the loss in the second outside sheath in addition to eq. 32 and eq. 34 of the previously mentioned *Electric Journal* article. Using the notation of that article, let

$$P_o = A_{co} + B_{co} + C_{co} + \ldots$$

$$P_n = A_{dn} + B_{dn} + C_{dn} + \ldots \quad n \neq 0$$

$$\frac{\text{Loss in sheath of second outside cable}}{\text{Loss in conductor at zero frequency}} = \frac{a^2}{c\,t} \left[2\,|P_o|^2 + |P_1|^2 + |P_2|^2 + \ldots + |P_n|^2 + \ldots \right] \tag{12}$$

Various problems in proximity effect and shielding in wires and thin tubes can be solved by these methods. Sheath losses are of sufficient importance to warrant being considered in all cases, even though frequently it will be desired only to compute the losses to show that they are practically negligible. In other cases, however, the effects are of engineering importance, and the design of conductors will depend upon the values computed.

Harmonic Generation by Grid Circuit Distortion

THE USUAL vacuum tube harmonic generators are fundamentally high distortion amplifiers operated under conditions of grid bias and plate voltage which, to distort the input voltage wave, utilize the non-linear relation between plate voltage and plate current. A paper published in the June 1931 issue of the A.I.E.E. TRANSACTIONS (see footnote) gives the result of an investigation into the possibilities of using the non-linear grid voltage-current characteristic to produce harmonics. Grid distortion can be utilized by operating the tube so that the grid goes positive for a part of each fundamental frequency cycle and then inserting in series with the grid lead an impedance across which the grid current impulses produce a voltage drop rich in harmonics, which then is amplified in the plate circuit.

The grid circuit distortion harmonic generator has the advantages of producing the harmonic in one circuit and developing the power in another, combined

---

Abstracted from "Harmonic Generation by Means of Grid Circuit Distortion" (No. 30-144) by F. E. Terman, (Asst. Prof. Elec. Engg., Stanford University, Calif.) D. E. Chambers (General Electric Co., Schenectady, N. Y.) and E. H. Fisher (Research Assistant, Stanford University, Calif.). Originally presented at the A.I.E.E. Pacific Coast convention at Portland, Ore., Sept. 2-5, 1930 (Eighth District 1930 prize paper). Published in A.I.E.E. TRANSACTIONS, V. 50, No. 2, June 1931, pp. 811-17.

with the very high distortion properties of the grid circuit. The result is that the grid distortion harmonic generator develops from 100 to more than 1,000 times as much power on the higher harmonics as does the usual plate distortion generator. Thus, when using a suitable parallel resonant circuit as the distorting grid impedance, a steady output of 135 volts effective has been obtained from a radio receiving tube on the 22nd harmonic. When the grid impedance consists of a large inductance it is possible to generate simultaneously at least 1/20th milliwatt of power on every harmonic up to the 50th. The grid circuit input power required to give these results is several hundred milliwatts in the case of the parallel resonant circuit, and considerably less when a grid inductance is used.

The paper gives the mechanism of operation, illustrated with oscillograms and harmonic spectra, and includes a discussion of the effect of circuit conditions on the operation of the grid distortion generator.

Discussion offered incident to the original presentation of this paper pointed out that:

> "In view of the fact that all of the results discussed in the paper are for a low fundamental frequency, it may be of interest to mention some work done . . . . at frequencies above 3,000,000 cycles, using tubes having ratings up to 250 watts . . . . The grid distortion harmonic generator using tuned grid impedance is characterized by a harmonic output that decreases very slowly as the order of the harmonic is increased. The result is that while the grid distortion method of harmonic generation has little, if any, advantage over the usual arrangement on the second and third harmonic, it is much superior on higher harmonics . . . . operative at fundamental frequencies above 3,000 kc., although adjustments were . . . . critical with unneutralized circuits. . . . a reasonable amount of power (has been obtained) on 8 meters with a generator drive by an 80-meter crystal."

The Trend in Dielectric Research

A résumé of some of the important advances made during the past year in the fields of physics and chemistry as applied to the fundamental theory underlying successful electrical insulation.

By
JOHN B. WHITEHEAD
Fellow A.I.E.E.
The Johns Hopkins University, Baltimore

THE PAST YEAR has been exceptionally rich in the results of dielectric research. Rather than attempt a review of all the new work which has come to my attention, I prefer to point out what seems to me to be an outstanding feature of the year's work, namely, an unusual intensity of the study of insulating liquids and some of the outstanding results thereof.

Several investigations are under way on the electrical properties of pure hydrocarbon liquids. From one of these there is some indication of a correlation between conductivity, as measured with continuous potential, and well recognized molecular properties. For the most part, however, the outstanding results of experiments of this character are to show that it is always possible, by further distillation and purification, to lower the conductivity still further. Values of conductivity of 10^{-18} and 10^{-19} mhos part are reported. These values always pertain to the long-time continuous voltage measurement and the volt-ampere characteristics show a pronounced saturation condition.

From the standpoint of such desirable insulating qualities as high dielectric strength, low dielectric loss, and low rate of deterioration due to whatever cause, these low values of conductivity are no indication of special value. In the matter of dielectric loss, for example, such pure liquids show losses under alternating stress which are far greater than may be accounted for by the final conductivity. The losses are completely accounted for, however, by an initial brief and constant conductivity which may be measured by oscillograph as shown by experiments in my own laboratory at Johns Hopkins University. The nature and type of the ions involved in this initial conductivity as yet are uncertain and present an interesting and important problem. It is of special interest to note that certain highly refined oils in the commercial class may, by similar treatment, have their final conductivity reduced to the same order of magnitude as that pertaining to the chemically pure simple hydrocarbon. In these cases, the ratio of the initial (0.002 to 0.01 sec.) to final (1 min. or more) conductivity may be as great as 500:1.

Essentially full text of the annual report of Doctor Whitehead as chairman of the committee on electrical insulation, division of engineering and industrial research, National Research Council, as presented at the fourth annual meeting and conference of that committee held at Harvard University, Cambridge, Mass., November 13 and 14, 1931.

The value of this ratio for the commoner, but good, insulating oils is from 4:1 to 10:1. The great differences in these ratios is caused by the differences in values of the final conductivities. The initial conductivity of the highly purified liquids approaches in value that of the commoner oils. In all cases a dielectric loss in the oil alone is accounted for completely by the initial conductivity.

COLLOID THEORY OF DIELECTRIC BEHAVIOR

There is increasing evidence that the electric ions involved in the dielectric loss in oils are larger than molecules. Attention already has been called to the possibility of this by Prof. J. W. Williams of the University of Wisconsin. In a series of papers stretching over the last few years, Professor Böning of Tung-Chi University has developed a theory of dielectric behavior based upon the properties of colloids, which he has applied experimentally and qualitatively, at least, to all the important phenomena appearing in the application of dielectrics as insulators. Briefly, the theory is as follows: All liquid insulators such as oil contain traces of colloidal particles the surfaces of which attract electric ions of one sign and hold them tight through the phenomenon of adsorption. The charges may be positive or negative according to the material, and the charged colloidal particles attract to themselves liquid ions of the opposite sign, of which there always are some present. The aggregate, therefore, consists of a double layer of opposite charges of which, however, the outer layer is very much more loosely bound than the inner. Under a sufficiently strong electric field the outer layer is detached and passes relatively rapidly to one electrode. The charged colloid particles thus left, owing to their size and mass, move slowly towards the opposite electrode. In the neighborhood of that electrode these particles may accumulate, forming a space charge, and thus reducing the field in the middle region and raising it near the electrode.

Experimental evidence of the presence of these space charges was presented several years ago by Whitehead and Marvin, and other similar evidence has been presented more recently by Schaefer. Böning recently has shown experimentally the presence of an increase of hydrostatic pressure under one electrode due to the accumulation of space charges. He invokes this phenomenon as an explanation of a condition sometimes observed in high voltage cables in which the compound appears to have migrated away from the central conductor. The space charges have low mobility and are evident only in studies with continuous voltage. The space charges as such do not accumulate at ordinary alternating frequencies, say 60 cycles, and the losses in oils at these frequencies are due to the oscillatory or perhaps rotatory motion of the particles or aggregates. They may be removed temporarily by the long application of a continuous field with consequent temporary reduction of loss.

COLLOIDS VS. DIELECTRIC STRENGTH

The influence of the presence of colloids upon the dielectric strength of oils also is being studied. According to Böning, as the amount of colloid material in purified insulating oils of several types increases up to 0.02 per cent there is a sharp reduction of dielectric strength to about 80 per cent of that of the pure oil. Greater proportions of colloid material, however, seem to have no increased effect. The breakdown strength under continuous voltage is 60 per cent of that under alternating stress. These results are said to be in general accord with the theory of space charges arising in the adsorption of ions of one sign and the resulting space charge and high stress near one electrode. Beyond a certain concentration of colloid particles there is no further lowering of dielectric strength because the particles tend to aggregate in large groups with corresponding reduction of the total adsorbing surface.

Further light on the nature of the breakdown of liquids is found in one of the frequent papers by Inge and Walther describing studies of the dielectric strength of xylol when carefully freed of dissolved gases by successive distillation. When so prepared, the breakdown strength of this liquid is independent of the pressure over a wide range, and independent of temperature for continuous and impulse voltages. There is, however, a continuous decrease of the breakdown alternating voltage with increasing temperature. The conclusion is reached that the breakdown in liquids is associated with the boiling point. Gas lowers the boiling point and facilitates breakdown. It would appear that the lowering of breakdown under alternating stress is due to increased local temperature caused by the back-and-forth motion of the colloid particles previously referred to, thus leading to breakdown, somewhat in accordance with the proposal of Gunther-Schultz. As related to this question of the picture of the nature of breakdown, there also may be mentioned the interesting report by Gemant of the photographic record of tiny local discharges within the oil before final failure.

LOW FREQUENCY LOSSES

Several papers have appeared discussing the possibility that dielectric losses at low frequencies may be occasioned by polar-molecular orientation in the Debye sense, as suggested by Kitchin and Mueller two years ago. Of these may be mentioned especially the work of Kirch and Riebel, who have reported several studies on oil-resin mixtures in various properties over a range of frequency from 50 to 10,000 cycles and in the temperature range from −30 to −160 deg. cent. These authors present a qualitative analysis of their results strongly supporting their proposal that the changes in power factor and dielectric constant with temperature and frequency are due to dipole orientation.

Ornstein and Willemse have presented other evidence in favor of molecular orientation as a cause of dielectric loss. They measure the Kerr effect, the dielectric loss, the temperature coefficient of dielectric constant, and the viscosity of a basic petroleum oil and eighteen different samples or cuts from the same oil by the separation of different compounds and their successive purification. Their results are presented in a series of diagrams in which the samples are arranged in horizontal rows, the several rows representing different groups of definite chemical character and the samples in each row being of different degrees of refinement. Correlation now is looked for in the changes in those electric properties dependent upon polar orientation as between the various groups and the respective samples in each group. Close correlation is found between changes in the value of the Kerr constant, the temperature change of dielectric constant, and in the values of dielectric loss, as well as in other properties. The whole presents a very convincing picture.

However, sharp exception to these proposals has been taken by A. Gemant in several papers, as well as in his interesting text, "Electrophysik der Isolierstoffe." In particular, he recently has reported a series of studies, similar to those of Kirch and Riebel, in which he shows that the oil carefully freed of colloids shows also the power factor variation attributed to polar molecules and that the increases due to the addition of colloid material by no means are proportionate to the amounts added. Further, he shows that similar changes may be brought about by the addition of non-polar impurities. He presents an equally convincing picture that the effect in question may be accounted for by the conductivity due to impurities and the consequent variations in structure, and that the variations of loss and power factor in the low temperature range for oils are in accordance with the Maxwell theory of absorption as extended by Wagner. He reaches the conclusion that losses due to polar molecules can occur only in frequencies at 10^4.

If time permitted, I should like to review briefly the important contributions from Rogowski, Joffé, Inge and Walther, and von Hippel, on the conductivity and electric breakdown in crystals. These contributions constitute notable extensions of present knowledge of the mechanism of molecular failure under electric stress. Reference to these and to all other papers mentioned will be found in the list which accompanies this report. These indicate that, as stated previously, the past year has been exceptionally rich in the results of dielectric research; it is extremely interesting to note also that the studies of engineers engaged in the direct application of dielectrics as insulators are approaching and supporting each other to a far greater extent than ever before.

Monograph Publication

One of the most important accomplishments of the year has been the appearance of the first of a series of monographs on dielectrics and insulation, which are to be published under the auspices of the N.R.C. committee on electrical insulation. The title of this first volume is "The Nature of a Gas," and its author, Prof. L. B. Loeb. The publisher is John Wiley & Sons. This is a remarkably clear and interesting exposition of recent knowledge and theory of the electrical properties of gases. It constitutes a most auspicious opening of a series which should be of great value, and the extension of which will constitute one of the committee's chief future efforts. Other monographs now in preparation are:

Electric Discharge in Gases, K. T. Compton and Irving Langmuir.

Conduction in Gases, J. Slepian and R. G. Mason.

Liquid Dielectrics, Dr. Andreas Gemant.

Solid Dielectrics, C. F. Hill, W. S. & M. Co.

The Electrical Properties of Glass, Dr. J. T. Littleton, Corning Glass Works.

Chemical Effects in Electric Discharge, George Glockler and Doctor Lind.

Bibliography

In presenting the following bibliography, no attempt has been to make it all-inclusive, and minor errors and inconsistencies may have crept in. It is believed, however, to contain many important publications on dielectric research and related subjects.

Physics, Chemistry and Theory

X-Ray Studies of Motions of Molecules in Dielectrics Under Stress, R. D. Bennett. *Jl. Franklin Inst.*, April 1931, p. 481. (Shows that after solidifying under stress paraffin gives an unsymmetrical halo when an x-ray beam passes through. No definite conclusions except molecules shifted.)

Conductivity of Crystals, A. Joffe. *Zeits. Phys.*, 62, 1930, p. 730. (Opposing Smekal and Rogowski.)

Concentrated Space Charges in Iceland Spar, A. Joffe. *Zeits. Phys.*, 66, 3, 4, 1930, p. 148. *Science Abstracts 1348.* (The concentrated high voltage space charge and its distribution in a thin cathode layer have been directly measured by grinding off the surface.)

Dielectric Polarization of Pure Organic Compounds, Morgan and Lowry. *Jl. Phys. Chem.*, Nov. 1930. (A series of measurements of molecular moments. No special bearing on insulating properties typical of a number of such studies. Connection not obvious as yet.)

Currents in Dielectrics, G. Guebeu. *Phil. Mag.*, 69, Feb. 1931, p. 405. (Mathematical development of currents in dielectrics due to polar molecules and due to ionic conduction; proposes an expression made up of their sum for total dielectric current. No experiments or check.)

Polar Molecules, S. O. Morgan. Washington meeting of N.R.C. committee on electrical insulation, Nov. 1930.

Theory of Absorption, Loss, Etc., Murphy Lowry, work at Bell Telephone Laboratories.

Passage of Electricity Through Solids, Nasledow and Scharawsky. *Ann. Phys.*, 5, 4, 1930, p. 429. (Polarization e.m.f. and appl. .m.f.—x-radiation increases residual charge and slower decay of charging current.

Dipole Theory, S. Whitehead. *Phil. Mag.*, 9, 1930, p. 865.

The Dependence of Polarization E.M.F. and True Conductivity of Crystals on the Field Strength, Berau and Quittner. *Zeits. Phys.*, 64, 11 and 12, 1930, p. 760.

Dielectric Polarization in Liquid Mixtures, N. N. Pal. *Phil. Mag.*, 63, 10, 1930, p. 265.

Space Charge, Colloids, and Properties of Dielectrics

Space Charge, Colloids, and Properties of Dielectrics

Oil Resin Mixtures, Bormann and Gemant. *Siemens, Konz.* (Power factor maximum at lower temperatures a Maxwell-Wagner and not a Debye effect.)

Properties of Oil Resin Mixtures, Kirch and Riebel. *Arch. Elek.*, 24, Nov. 7, 1930, p. 553.

Colloidal Anomalies of Petroleum Oils, Prausnitz. *Kolloid Zeits*, 51, June 1930, p. 359.

Cataphoresis in Rotating Fields, Colloid Parts, Pugh and Swartz. *Phys. Rev.*, Nov. 1.

Field Distribution in Liquids, Schaefer. *Zeits. Physik*, 62, 9, 10, p. 585.

Importance of Colloid Behavior of Insulating Liquids and Solids, J. W. Williams. Lecture at Washington meeting of N. R. C. committee on electrical insulation, Nov. 1930.

Breakdown

Influence of Colloid Suspensions on Dielectric Strength of Oils, P. Boning. *Zeits. fur Tech. Phys.*, 4, 1931, p. 200. (Up to 0.02 per cent by weight colloid asphalt reduces dielectric strength to about 80 per cent value for pure oil, thereafter no further reduction with more colloids.

Dielectric Strength of Degassed Liquids, L. Ingo and A. Walther. *Zeits. fur Phys.*, 9, 1930, p. 369. (Dielectric strength independent of pressure in degassed liquids—d-c. and a-c. and impulse. D-c. and impulse independent of temperature, but a-c. decreases with increasing temperature.)

Breakdown in Solids, Inge and Walther. *Arch. Elek.*, 25, Jan. 27, 1931, p. 21. (Showing that surface gradients at breakdown may be much higher for small radius conductors than those for parallel electrodes, notably in sulphur, suggesting corona effect in gas.)

Space Charge and the Breakdown of Gases, Rogowski. *Arch. Elek.*, Dec. 5, 1930, p. 679. (Positive space charge at negative electrode leads to the avalanche type of generation of new electrons; computation of the condition leading to rough agreement with the theory.)

The Theory of Thermal Breakdown in Solid Dielectrics, P. H. Moon. A.I.E.E. Trans., V. 50, 1931, p. 1008. (Discussion of theory as developed by Fock; extension and experimental results.)

Losses and Power Factor; Deterioration of Insulation

Influence of Colloid Suspensions on Dielectric Strength of Oils, P. Boning. *Zeits. fur Tech. Phys.*, 4, 1931, p. 200.

Influence of External Corona Discharges on Life of Impregnated Paper Cables, *Elec. Testing Lab. Report 31 W-3912.*

Power Factor Tests of Bushings and Insulators as Indications of Life. *Elec. World*, Aug. 29, 1931.

Dielectric Loss in Oils, A. Gemant. *Zeits. fur Tech. Phys.*, 12, 1930, p. 544. (Criticizing Ornstein and Willemse.)

Influence of Pressure on Dielectric Strength of Dry Paper, A. Gemant. *Arch. Elek.*, 25, 1931, p. 181. (At low pressures paper is stronger than air, at high pressures less so.)

Electrophotographie von Isolierstoffe, A. Gemant. *Zeits. Tech. Phys.*, 5, 1931, p. 250.

Paragutta, New Material for Submarine Cables, Kemp. *Bell Syst. Tech. Jl.*, Jan. 1931.

The Gas Content of Paper in Its Bearing on the Electrical Properties, Kogert. *Kunstoffe*, 21, No. 2, Feb. 1931. (The evolution of gas under oil is shown to be due to moisture, to acetone solubility, and to mechanical structure. The more rapid the gas evolution with increase of temperature, the poorer the electrical properties of the paper.)

Electric Loss and Electric Dipole Moment in Transformer Oil, Ornstein and Willemse. *Zeits. fur Tech. Phys.*, 9, 1930, p. 345. (Correlation of several factors over frequency range 50 to 10^6 cycles, all pointing to dipole loss.)

Some Electrical Characteristics of Cable Oils, H. H. Race. A.I.E.E. Paper No. 31-47. (Oil test cell; correlation of a-c. and d-c. 1-min. measurements.)

Oil Losses at High Frequencies, Vogler. *Eleck. Nach. Tech.* (Losses in oils at high frequencies 10^6 to 1.3×10^7, calorimeter method; power factor is indication of frequency and losses; no evidence of molecular polarity.)

Tests of Insulating Oils, Weiss and Solomon. *R.G.E.*, 28, July 2, 1930, p. 61. (Extensive study of oxidation and depreciation.)

Dielectric Research, Welo's work with the General Cable Corp.

Conductivity of Insulating Oils II, J. B. Whitehead. A.I.E.E. Trans., V. 50, No. 2, June 1931, p. 695.

Fundamental Properties of Impregnated Paper, J. B. Whitehead and W. B. Kouwenhoven. A.I.E.E. Trans., V. 50, No. 2, 1931, p. 699.

Simultaneous Faults on Three-Phase Systems

FROM published records of flashovers on double-circuit towers which have tripped out both circuits, and from opinions expressed by operating engineers of various power companies, approximately 20 per cent of faults occurring on double-circuit towers involve conductors of both circuits. In addition to these, instances have been reported where faults in substations have involved conductors of circuits not on the same towers. "It seems worth while therefore," states Edith Clarke (A'23) of the General Electric Company, Schenectady, N. Y., in a current A.I.E.E. paper, "to have in convenient form, methods for calculating short-circuit currents, and of determining the stability limit of a system when faults occur simultaneously at two separate and distinct points of the system."

The method of symmetrical components, introduced by C. L. Fortescue (A.I.E.E. PROCEEDINGS, Vol. 37, June 1918, p. 629-716) and now being used extensively to determine short-circuit currents and stability limits during transient conditions, have been extended by the author to apply to three-phase systems during simultaneous faults at two or more points. In the positive phase diagram, a general equivalent circuit is developed to replace two simultaneous faults involving any combination of the six conductors. An approximate equivalent circuit to be used with a d-c. calculating table when resistance is neglected also is given. In addition, special equivalent circuits are employed to replace two simultaneous faults and the lines upon which they occur, when these lines are unloaded feeders radiating from a common point or lines of equal impedances bused at both ends.

In the discussion on this paper (A.I.E.E. TRANSACTIONS, Vol. 50, September 1931, p. 939-41), the author's methods were shown to be of great practical value especially where two or more circuits are strung on the same towers. Some cases of trouble were reported on faulty circuit structures which involved two lines going to entirely different parts of the system. The paper enables protection engineers to work out the complete story of any type of simultaneous fault in quite a reasonable length of time, from which information relay settings may be established. Although developed specially for use with grounded systems, the discussion brought out also the fact that the method may be adapted to the calculation of fault currents and voltages on ungrounded systems which are quite common in Europe.

Abstracted from "Simultaneous Faults on Three-Phase Systems" by Edith Clarke, (No. 31-60) presented at the A.I.E.E., Middle Eastern District meeting, Pittsburgh, Pa., March 11-13, 1931.

Of Institute and Related Activities

Winter Convention Presents Elaborate Program

CURRENT engineering improvements in the art, resulting from field, laboratory, and operating experiences will be presented and discussed in the fourteen technical sessions to be held during the A.I.E.E. winter convention, with headquarters in the Engineering Societies Building, 33 West 39th Street, New York, N. Y., January 25-29, 1932. In addition to the excellent technical program there will be interesting inspection trips and numerous entertainment features, with a specially arranged program for the visiting ladies.

TECHNICAL SESSIONS

The technical sessions have been planned so that the interests of any groups may not conflict at parallel sessions and yet subjects of interest to the same groups may be found scheduled close together. Thus those engaged in the fields of power generation, transmission, and distribution will find the sessions on protective devices, distribution circuit lightning protection, selected subjects, and system stability, of particular interest. Those chiefly interested in theory should find the latter session to be of particular interest as well as the sessions on instruments and measurements, general circuit theory, and research. All of the sessions so far mentioned will be held during the first three days of the convention. Designers and electrical manufacturers should find much material of unusual interest in the sessions scheduled for Thursday and Friday; namely two sessions on electrical machinery, one on transportation, and another on electric welding. A session on electrochemistry and electrometallurgy which is of both theoretical and basic practical interest also will be presented on Thursday morning. Friday will be devoted primarily to communication subjects although the papers presented in the symposium on time, and time services, should have a broad general appeal. With a program of such broad scope and timely interest those attending should have little difficulty in finding sessions of unusual interest along their particular lines of endeavor.

ENTERTAINMENT

A buffet supper and smoker with entertainment will be held on Tuesday evening. On the following evening both the Edison Medal and the John Fritz Medal will be presented to the respective medalists. On Thursday evening the annual social event, the dinner dance, will be held. In addition, there will be a number of interesting inspection trips and the special program for the ladies in attendance; more information pertaining to these features will be announced at a later date. Monday and Friday evenings have been left open to afford out-of-town guests an opportunity for theater going, the visiting of friends or making other engagements.

REDUCED RAILROAD RATES

Under the certificate plan reduced railroad rates will be available to members and guests who attend the convention; only half fare need be paid on a return trip over the same route, provided a total of at least 100 certificates are deposited at the registration desk. Rates apply to all who attend the convention and to dependent members of their families. Each member or guest should obtain a certificate when purchasing his one-way ticket to New York, explaining to the ticket agent that he wishes the certificate authorized by the passenger associations for the winter convention of the American Institute of Electrical Engineers.

On arriving at the convention the certificate should be deposited at the registration desk. There it will be held for validation by a railroad representative and if 100 or more certificates are validated, these certificates will be returned to the owners. By presenting the validated certificate when purchasing return ticket, only half fare will be charged. Local ticket agents should be consulted regarding conditions affecting this plan, as it applies only within certain dates, depending upon the territory. *Everyone* whose one-way fare is more than 66 cents *should get a certificate* whether or not he intends to use it. *By neglecting to do so others may be deprived of considerable saving.*

COMMITTEES

The 1932 winter convention committee is constituted as follows: E. B. Meyer, *chairman*; O. H. Caldwell, H. P. Charlesworth, Harold C. Dean, W. H. Harrison, C. R. Jones, G. L. Knight, C. E. Stephens and R. H. Tapscott.

Chairmen of the subcommittees are: C. E. Stephens, convention executive committee, with C. R. Jones as vice-chairman; G. W. E. Draper, smoker; E. J. Johnson, dinner dance; W. R. Smith, inspection trips; and Mrs. E. B. Meyer, ladies' entertainment.

SCHEDULE OF EVENTS

Monday morning and evening have been left open for committee meetings. Capital letters A, B, etc., denote technical sessions.

Monday, January 25

10:00 a. m.	Registration
2:00 p. m.	Opening of Convention
	A—Protective Devices
	B—Instruments and Measurements

Tuesday, January 26

10:00 a. m.	C—Symposium on Distribution Circuit Lightning Protection
	D—General Circuit Theory
2:00 p. m.	E—Research
	F—Selected Subjects
6:00 p. m.	Buffet Supper and Smoker

Wednesday, January 27

10:00 a. m.	G—Symposium on System Stability
1:15 p. m.	Inspection Trips
2:00 p. m.	Board of Directors Meeting
8:30 p. m.	Edison Medal and John Fritz Medal Presentations

Thursday, January 28

10:00 a. m. H—Electrical Machinery
I—Electrochemistry and Electrometallurgy
2:00 p. m. J—Electrical Machinery
K—Transportation
7:30 p. m. Dinner Dance

Friday, January 29

10:00 a. m. L—Symposium on Time and Time Services
2:00 p. m. M—Communication
N—Electric Welding

Tentative Technical Program

Monday—2:00 p. m.

A—Protective Devices

A New High Speed Distance Relay with Composite Impedance—Reactance Characteristic, S. L. Goldsborough and W. A. Lewis, Westinghouse Elec. & Mfg. Co.

The Theory of Oil Blast Circuit Breakers, D. C. Prince, General Electric Co.

*The Practical Application of the Oil Blast Principle of Circuit Interruption, R. M. Spurck, General Electric Co.

*Recent Developments in Arc Rupturing Devices, R. C. Van Sickle and W. M. Leeds, Westinghouse Elec. & Mfg. Co.

Extinction of A-C. Arcs in Turbulent Gases, T. E. Browne, Jr., Westinghouse Elec. & Mfg. Co.

B—Instruments and Measurements

High Voltage Bridge for Measurements of Cable with Grounded Sheaths, C. L. Dawes and A. F. Daniel, Harvard University

A High Sensitivity Power Factor Bridge, W. B. Kouwenhoven and Alfredo Banos, Jr., The Johns Hopkins University

*Capacitance and Power Factor Measurement by the Capacitance Bridge, R. P. Siskind, Harvard University

*Aging and Elastic Hysteresis Instrument Springs, R. W. Carson and P. MacGahan, Westinghouse Elec. & Mfg. Co.

*An Automatic Oscillograph, C. M. Hathaway and R. C. Buell, General Electric Co.

*The Photoelectric Recorder, C. W. LaPierre, General Electric Co.

Tuesday—10:00 a. m.

C—Symposium on Distribution Circuit Lightning Protection

*Lightning Protection of Transformer Secondaries, C. Francis Harding and C. S. Sprague, Purdue University

*Field Studies of the Protection of Distribution Transformers by Lightning Arresters, Including the Effect of Interconnection, K. B. McEachron, General Electric Co.

*The Protection of Distribution Transformers from Failures Due to Lightning, A. M. Opsahl, Westinghouse Elec. & Mfg. Co., A. S. Brookes and R. N. Southgate, Public Service Electric and Gas Co.

*Studies in Lightning Protection on 4,000-Volt Circuits—III, D. W. Roper, Commonwealth Edison Co.

*Investigation of Lightning Protection for Distribution Transformers, T. H. Haines and C. A. Corney, The Edison Electric Illuminating Company of Boston

*Distribution System Lightning Studies by Philadelphia Electric Company, H. A. Dambly, H. N. Ekvall, and H. S. Phelps, Philadelphia Electric Co.

D—General Circuit Theory

Equivalent Circuits, F. M. Starr, General Electric Co.

Transient Oscillations of Mutually Coupled Windings, L. V. Bewley, General Electric Co.

The Geometrical Circuits of Electrical Networks, R. M. Foster, American Tel. & Tel. Co.

Tuesday—2:00 p. m.

E—Research

Some Fundamental Theory and Experiments on Electrical Precipitation, A. W. Simon and L. C. Kron, Tennessee Coal, Iron and Railroad Co.

Radio Interference from Corona on High Voltage Insulators, F. O. McMillan, Oregon State Agricultural College

*Predetermination of the A-C. Properties of Dielectrics from the Continuous Potential Characteristics, J. B. Whitehead and A. Banos, Jr., Johns Hopkins University

The Breakdown of Glass with Alternating Potentials, N. D. Kenney, A. M. Luery and J. D. Moriaty, Standard Cable Corp.

Relationships among the Magnetic Properties of Magnet Steels and Permanent Magnets, K. L. Scott, Western Electric Co.

F—Selected Subjects

*Introductory Statement—Steam *vs.* Electrically Driven Auxiliaries for Steam Power Stations, F. H. Hollister, Sargent and Lundy, Inc.

Steam Driven Auxiliaries for Power Plants, W. Poole Dryer, Stone and Webster, Inc.

Electrically Driven Auxiliaries for Steam Power Stations, L. W. Smith, Sargent and Lundy, Inc.

*An Improved Type of Limiting Gap for Protecting Station Apparatus, A. O. Austin, Ohio Insulator Co.

Wednesday—10:00 a. m.

G—Symposium on Stability

*Proposed Definitions of Terms Used in Power Stability Studies—Report of Subject Committee on Definitions, H. K. Sels, Chairman

*Recommended Current Decrement Curves—I, W. C. Hahn, General Electric Co., and C. F. Wagner, Westinghouse Elec. & Mfg. Co.

*Recommended Decrement Curves—II, W. C. Hahn, General Electric Co.

*Recommended Decrement Curves—III, C. F. Wagner and S. H. Wright, Westinghouse Elec. & Mfg. Co.

*Operating Experience of the Philadelphia Electric Company System from the Stability Point of View, R. A. Hentz and J. W. Jones, Philadelphia Electric Co.

Thursday—10:00 a. m.

H—Electrical Machinery

*An Induction Motor With Paralleled Rotor and Stator, A. G. Conrad and R. G. Warner, Yale University

*Some Considerations in the Design of Damper Windings for Synchronous Motors, C. C. Shutt, Westinghouse Elec. & Mfg. Co.

*Surge-Proof Transformers, H. V. Putman, Westinghouse Elec. & Mfg. Co.

*Effect of Transient Voltages on Power Transformer Design IV—Transformation of Lightning Waves to Secondary Windings, K. K. Palueff and J. H. Hagenguth, General Electric Co.

I—Electrochemistry and Electrometallurgy

Power Losses in Electrolytic Condensers, F. W. Godsey, Jr., The Safety Car Heating and Lighting Co.

Film Characteristics of Electrolytic Condensers, F. W. Godsey, Jr., The Safety Car Heating and Lighting Co.

*The Effect of Polar Molecules in Dielectrics, W. N. Stoops, Westinghouse Elec. & Mfg. Co.

*Cobalt Magnet Steel, P. H. Brace, Westinghouse Elec. & Mfg. Co.

Thursday—2:00 p. m.

J—Electrical Machinery

*Commutation Considered as a Switching Phenomenon, R. E. Hellmund and L. R. Ludwig, Westinghouse Elec. & Mfg. Co.

Equalizing Currents in the Armature of a D-C. Machine, R. M. Baker, Westinghouse Elec. & Mfg. Co.

Calculation of the No-Load Damper Winding Loss in Synchronous Machines, E. I. Pollard, Westinghouse Elec. & Mfg. Co.

*Mathematical Theory of Sine Wave Generators, L. P. Shildneck, General Electric Co.

K—Transportation

Engineering Features of "Three Power" Locomotives, F. H. Brehob and F. H. Craton, General Electric Co.

Motors for 3,000-Volt D-C. Multiple Unit Cars, J. C. Aydelott, General Electric Co.

The Temperature Rise of Ventilated Railway Motor Armatures, D. A. Lightband, Westinghouse Elec. & Mfg. Co.

*High Capacity Rectifier Efficiency Improved by Sectionalization, A. L. Atherton, Westinghouse Elec. & Mfg. Co.

*European Railway Electrification, W. S. Gordon, Jr., Railway Electrical Engineer, Montclair, N. J., and E. Jaboolian, formerly with Jackson & Moreland, Hoboken, N. J.

Friday—10:00 a. m.

L—Symposium on Time and Time Services

†Astronomical Aspects of Time, E. W. Brown, Yale University

*Modern Developments in High Precision Clocks, A. L. Loomis, Loomis Laboratories, and W. A. Marrison, Bell Telephone Laboratories, Inc.

*The Time Service of the U. S. Naval Observatory, J. F. Hellweg, U. S. Naval Observatory

*Time Services of the Telegraph Companies, G. W. Jansen, Western Union Telegraph Co.

*Time Services of the Power Companies, H. E. Warren, Warren Telechron Co.

Friday—2:00 p. m.

M—Communication

†New Key West-Havana Carrier Telephone Cable, H. A. Affel, American Tel. & Tel. Co., W. S. Gorton and R. W. Chestnut, Bell Telephone Laboratories, Inc.

†The Development of a Hand Set for Telephone Stations, W. C. Jones, Bell Telephone Laboratories, Inc.

†An Automatic Concentration Unit for Printing Telegraph Circuits, G. S. Vernam, International Communications Laboratories, Inc.

†Direct Printing Over Long Non-Loaded Submarine Telegraph Cables, M. H. Woodward, and A. F. Connery, International Communications Laboratories, Inc.

†Carrier Applications to a Telegraph Plant, R. E. Smith and L. A. Kelley, International Communications Laboratories, Inc.

†Direct Solutions of Coupled Tuned Circuits, L. A. Kelley, International Communications Laboratories, Inc.

N—Electric Welding

Forces of Electric Origin in the Iron Arc—An Explanation of Overhead Welding, F. Creedy, R. O. Lerch, P. W. Seal and E. P. Sordon, Lehigh University.

*An Improved A-C. Arc Welder, A. M. Candy, Westinghouse Elec. & Mfg. Co.

*The Fundamentals of the Design of Arc Welding Generators, K. L. Hansen, K. L. Hansen Engineering Co., Inc.

---

*These papers are under consideration for presentation at the winter convention, but up to the date of going to press, November 23, they have not been officially placed upon the program.

†These papers will not be published in advance form by the Institute but copies may be made available by the respective authors.

Kansas City District Meeting Well Attended

WITH a total registered attendance of 411 persons the South West District meeting held in Kansas City, Mo., October 22-24, 1931, was particularly noteworthy in the very active participation of Enrolled Students. The final tally of official registration showed 159 Members, 60 men guests, 19 women guests, and 173 students. All six of the District Sections—Dallas, Houston, Kansas City, Oklahoma City, St. Louis, San Antonio—were represented, as were also practically all of the District's fourteen Student Branches.

Although evening and Saturday sessions usually are not crowned with success, the two such sessions held at Kansas City were unquestionably successful if attendance may be taken as an index. Of the four technical sessions the Thursday afternoon and Saturday morning sessions were held in the roof garden ballroom of the Kansas City Athletic Club, while the Thursday evening and Friday morning sessions were held in the beautiful Thomas Alva Edison memorial auditorium in the new office building of the Kansas City Power and Light Company. The evening session in the power company's auditorium was in the nature of a public meeting featuring various angles of the St. Louis-Bagnell interconnection, supplemented by motion pictures of Bagnell Dam and powerhouse, and of the 129-mile "Lake of the Ozarks" created by the dam.

Opening Addresses

With A. E. Bettis, past vice-president (1926-28) as chairman, Dean G. C. Shaad, gave the opening address following the official welcome extended by Col. R. D. Garrett for Kansas City's Mayor, Bryce B. Smith. In his presentation Dean Shaad described the fundamentals of the Institute organization and the reasons underlying the promotion of District meeting activities. He pointed with some pride to the 12.5 per cent growth in Institute membership that has occurred in District 7 for the Institute year recently closed, and commended the District's newer and smaller sections for their active development work.

President C. E. Skinner in addressing the gathering expressed himself as also believing that the "future of engineering students is very bright indeed," pointing out with some emphasis the fact that electrical engineering graduates now are occupied in gainful pursuits in percentages higher than any other class of graduates. Doctor Skinner urged careful stock taking and careful planning for the future during the present period of business unrest, and urged a realization of the cyclic character of the situation. He read a report issued by the United States Secretary of Labor some 47 years ago which specifically made the prediction that (then) "the needs of the world now are more than adequately provided for and it is useless to look to the future for further large developments or profits." Doctor Skinner reviewed very briefly the advancements made in the ensuing 47 years stating that they should be index enough of what can happen during the next period of similar length.

National Secretary F. L. Hutchinson also spoke, emphasizing briefly the need of more constructive attention to the matter of technical advancement and less attention to such current non-productive phrases as "technological unemployment." Mr. Hutchinson pointed out that technical advancement inevitably provides for increases in employment and general productive activities which otherwise never would develop. As one specific example he cited the contributions of Thomas A. Edison, whose work has provided the basis for tremendous industrial activity employing hundreds of thousands of individuals.

Edison Memorial Program

To present a short Thomas A. Edison memorial program Chairman Bettis called upon two Edison Pioneers to speak briefly. Joseph F. Porter (M'87 and Member for Life) president of the Kansas City Power and Light Company, cited the difficulties with which Edison was faced in the early development and promotion of his ideas, calling attention to the value of reverses which necessitate close application to the work in hand. Bringing his reasoning down to date, he urged diligent individual application as an important means of overcoming the present economic disturbance. As a bit of interesting history he mentioned the fact that on November 14, 1881, agreements were signed with Thomas A. Edison giving L. K. Moore and Joseph Chick the right to use in Kansas City patented rights, machines, and associated power plant equipment, resulting in the completion in 1882 of Kansas City's first electric generating plant. William Hahn, Kansas City manager for the General Electric Company, described the basis on which the organization of Edison Pioneers was built and quoted their official aims. Concerning an everlasting memorial to Thomas A. Edison, Mr. Hahn said that "the electric industry is a true and everlasting monument to Edison."

Student Sessions

Two student sessions were held the first day of the meeting at which the following ten papers were presented:

Modulation by Means of a Class B Amplifier, H. D. Labrecht, University of Arkansas.

Michael Faraday—The Man, C. M. Brecheisen, University of Kansas.

Choice of Equipment for Petroleum Pump Stations, V. J. Sittel, Oklahoma A. & M. College.

Accumulation of High Potential Static Charges on Transmission Lines During Sand Storms, C. E. Houston, Texas Technological College.

Sound as Applied to Synchronized Talking Pictures, M. R. James, Missouri School of Mines and Metallurgy.

A Synchronous Contactor in Transient Study, S. P. Robertson, University of Texas.

Control of the Hot-Cathode Thyratron, J. V. Melton, Southern Methodist University.

Design and Construction of Radio Field Intensity Measuring Equipment, G. S. Hammonds, University of Oklahoma.

Carrier Current Communication Over High Voltage Power Lines, J. E. Shepherd, University of Missouri.

Television, W. R. Mitchell, Kansas State College.

Main Sessions

Of the four main sessions, two were devoted to transmission and distribution problems, one to communication, and one, as mentioned, to the St. Louis-Bagnell interconnection. Session chairmen were: D. D. Clarke (M'18) of the Kansas City Section, and District Vice-President G. C. Shaad (F'13) respectively for the two transmission and distribution sessions; Stanley Stokes (F'29) of the St. Louis Section, for the interconnection session; E. T. Mahood (M'28) of the Kansas City Section, for the communication session. All of the eighteen technical papers presented at the four sessions and not previously or contemporarily published in Electrical Engineering in comprehensive form were abstracted on p. 900-3 of Electrical Engineering for November 1931 and hence will not be discussed further here. Papers of both local and general interest were presented. All were well received and actively discussed, although the paucity of written discussion precludes the usual publication of a summarized review of discussion.

Entertainment

Under the influence a very evident air of spontaneous western hospitality, the social functions, staged under the direction of the local committees, were among the most wholly successful social affairs held this year in connection with major Institute meetings. Local sightseeing trips and inspection trips of a technical nature were available in wide variety; for the women there was a bridge luncheon, several excursions and other enjoyable activities; for those who wanted golf facilities, these were provided also. A dinner dance featuring particularly well planned entertainment and held in the grand ballroom of the Kansas City Athletic Club Friday evening proved a fitting climax for the social activities held in connection with the District meeting. A much appreciated part of the evening's program was the total omission of all speakers.

District 7 Executive Committee Convenes at Kansas City

During the recent District meeting in Kansas City, Mo., a meeting of the executive committee of the Institute's South West District was held on October 23, 1931. Present were: chairman and District vice-president, G. C. Shaad (Lawrence, Kans.); District secretary, R. W. Warner (Lawrence, Kans.); Section chairmen, G. A. Dyer (Dallas, Texas); E. M. Wise (Houston, Texas); George Fiske (Kansas City, Mo.); C. T. Almquist (Norman, Okla.); C. H. Kraft (St. Louis, Mo.); J. E. Woods (San Antonio, Texas); Section secretaries, S. M. Sharp (Dallas, Texas); J. S. Waters (Houston, Texas); R. M. Ryan (Kansas City, Mo.); C. E. Bathe (Oklahoma City, Okla.); C. H. Lankford (St. Louis, Mo.); acting Section secretary, I. A. Uhr (San Antonio, Texas); chairman of District committee on student activities, F. G. Tappan (Norman, Okla.).

In selecting a member to represent this District on the national nominating committee, C. T. Almquist (Norman, Okla.) was declared elected. A motion that Mr. Almquist go uninstructed was carried. G. A. Mills (Dallas, Texas) was nominated as candidate for the office of vice-president from the South West District to be voted upon at the coming spring election of officers. The following four additional members of the coordinating committee were elected: George Fiske (Kansas City, Mo.); S. M. Sharp (Dallas, Texas); C. H. Lankford (St. Louis, Mo.); and E. M. Wise (Houston, Texas). Also to serve on this committee W. L. Upson (St. Louis, Mo.) was elected from the student counselors.

Other matters of interest to the District were discussed, including the date and location of the next District meeting.

In the meeting of student counselors and student Branch chairmen, F. G. Tappen (Norman, Okla.) was elected to succeed W. P. Weinbach (Columbia, Mo.) as chairman of the District committee on student activities.

Directors Meet at Kansas City

A regular meeting of the Institute's board of directors was held at the Kansas City (Mo.) Athletic Club, Friday, October 23, 1931. Present were: *President*—C. E. Skinner, East Pittsburgh, Pa. *Vice-Presidents*—H. P. Charlesworth, New York, N. Y.; W. E. Freeman, Lexington, Ky.; W. B. Kouwenhoven, Baltimore, Md.; T. N. Lacy, Detroit, Mich.; P. H. Patton, Omaha, Neb.; G. C. Shaad, Lawrence, Kans. *Directors*—A. E. Bettis, Kansas City, Mo.; B. D. Hull, Dallas, Tex.; J. E. Kearns, Chicago, Ill.; A. M. MacCutcheon, Cleveland, Ohio. *National Secretary*—F. L. Hutchinson, New York, N. Y.

The minutes of the directors' meeting of August 4, 1931, were approved.

A minute in memory of Thomas A. Edison was adopted. (This minute was published in the November issue of ELECTRICAL ENGINEERING, p. 907.)

The board ratified actions taken by the executive committee, under date of September 28, 1931, on 46 applications for admission to the grade of Associate and five to the grade of Member; three for transfer to the grade of Member, and 35 for Student enrolment.

Reports of meetings of the board of examiners held September 23 and October 20, 1931, were presented and approved; upon the recommendation of that board, the following actions were taken on pending applications: 276 Students were enrolled; 59 applicants were elected to the grade of Associate and 12 to the grade of Member; 28 applicants were transferred to the grade of Member and two to the grade of Fellow.

Approval by the finance committee for payment of monthly bills amounting to $36,170.11 was ratified.

Upon the recommendation of the finance committee it was decided, because of present economic conditions, to omit the publication of a year book for 1932, and to suspend until further notice, payment of traveling expenses to provide for the Sections occasional addresses by prominent Institute members designated as "Institute lecturers."

A budget for the appropriation year of the Institute beginning October 1, 1931, submitted by the finance committee, was adopted.

Upon request of the executive committee of the North Eastern District, the board approved the dates May 4-7 for the 1932 District meeting to be held at Providence, R. I.

The following actions were taken upon the recommendation of the standards committee: "Standards for Metal Tank Mercury Arc Rectifiers" prepared by the sectional committee on mercury arc rectifiers, for which the Institute is sole sponsor, approved for submitting to the American Standards Association for approval as a tentative standard; a revision of paragraph 13-250 of A.I.E.E. Standard No. 13, "Transformers, Induction Regulators and Reactors," approved for submitting to the Electrical Standards Committee with the recommendation that it be incorporated in the revision of Standard No. 13 already submitted to that body.

Amendments to the by-laws were adopted canceling the name "Meetings and Papers Committee" wherever they occur in the by-laws and substituting "Technical Program Committee," and canceling the name "Law Committee" and substituting "Committee on Constitution and By-Laws."

Section 71 of the by-laws, relating to the functions of the law committee, was canceled and the following was substituted:

> Sec. 71. The committee on constitution and by-laws shall consist of five members and shall consider all matters relating to the constitution and by-laws of the Institute, including the legal status in connection therewith, also all other matters referred to it by the board of directors, the president, or the national secretary. The committee shall make reports and recommendations to the board of directors for action thereon and may consult legal and technical counsel with reference to any question before it.

A new section of the by-laws was adopted, as follows:

> Sec.—The committee on legislation affecting the engineering profession shall consist of fifteen members. It shall consider all matters relating to existing or proposed legislation which has an engineering content, and which concerns the welfare of the public or the practise of professional engineering. The committee shall also consider and report upon all other matters referred to it by the board of directors, the president, or the national secretary, and may consult legal counsel with reference to any question before it.

Upon the recommendation of the committee on economic status of the engineer a resolution was adopted urging Institute Sections to cooperate with other local groups of engineers in the organization of an engineers' unemployment relief committee in each community.

In accordance with the constitution and by-laws, the following five members of the board of directors were selected to serve on the national nominating committee: A. B. Cooper, B. D. Hull, W. B. Kouwenhoven, A. M. MacCutcheon, and C. E. Stephens.

The board confirmed the appointment by the president of P. M. Lincoln as a member of the Lamme Medal committee to fill a vacancy.

F. D. Newbury was reappointed a representative of the Institute on the Standards council of the American Standards Association for the three-year term beginning January 1, 1932; and H. H. Henline, A. M. MacCutcheon, and H. S. Osborne were appointed alternates for the year 1932. H. S. Osborne was appointed to act as alternate for any of the A.I.E.E. representatives on the Electrical Standards Committee. V. J. F. Brain, chief electrical engineer, Department of Public Works, Sydney, N.S.W., was appointed local honorary secretary of the Institute for Australia, to succeed H. W. Flashman, who is no longer located in Australia.

The following resolution was adopted in appreciation of the fourth gift to Engineering Foundation by Ambrose Swasey:

Whereas, Dr. Ambrose Swasey, Honorary Member of the A.I.E.E., has recently presented an additional fund of $250,000 to Engineering Foundation, which was founded in 1915 as a result of his vision and leadership, and to which he has now contributed a total of three-quarters of a million dollars for "the furtherance of research in science and engineering, or the advancement in any other manner of the profession of engineering, and the good of mankind," be it therefore

Resolved: That the board of directors of the American Institute of Electrical Engineers hereby expresses its deepest appreciation of Doctor Swasey's recent gift, a generous provision for the extension of the activities of the Foundation, and an admirable expression of his continuing faith in the importance of its accomplishments as well as its promise of even more important future contributions to the development of science and engineering.

The following resolution was adopted:

Resolved: That the board of directors hereby expresses its hearty appreciation of the effective services of the members of the District Meeting committee and its various subcommittees in arranging and carrying out, with gratifying success, the plans for the South West District meeting held in Kansas City, October 22-24, 1931.

Other matters were discussed, reference to which may be found in this and future issues of Electrical Engineering.

Unemployment Relief Plans Well Under Way

The following resolution, recommended by the A.I.E.E. committee on the economic status of the engineer, was unanimously adopted by the board of directors of the Institute at a meeting held in Kansas City, Mo., Oct. 23, 1931:

Whereas, it is desirable that the Institute cooperate in every movement that is already in progress to promote employment, and also to initiate within local communities a program that will contribute toward the relief of unemployed engineers;

Resolved: That this board recommends that each Section formulate and carry out a plan embodying substantially the following features:

1. The organization in each locality of a committee of engineers, preferably composed of representatives of all the engineering groups in the community.
2. This committee to collect and administer funds for purposes of loans and remuneration to deserving unemployed engineers.
3. A survey of the local engineers who are unemployed and in need of relief.
4. A survey of local opportunities for constructive work or employment, in which there may be utilized the services of the much larger group of unemployed, in addition to engineers; supported through the use of the community unemployment fund.
5. The preparation by the committee, by the aid of unemployed engineers as far as practicable, of engineering analyses, estimates, and organization requirements for such projects or work as the committee may endorse.
6. A forceful presentation by the engineers' committee of these projects to those in charge of the local civic unemployment activities, and the enlistment of their approval and financial support in promptly getting work started.
7. In carrying out the plan, each local Section of the Institute should work in close cooperation with local Sections of other national societies and with other local engineering groups; and, also, the general engineers' committee so organized should work in close cooperation with other local civic relief organizations.
8. In order that this plan shall be effective, it is essential that the local engineers' committees be carefully organized. A suggestion for such an engineers' unemployment committee is that it include some of the unemployed engineers, some good solicitors of funds, some good searchers for jobs, and some good organizers and administrators; and it is recommended that each committee have a chairman, a vice-chairman, a secretary, and treasurer, an executive committee to coordinate the work, a committee to administer the funds, make loans, arrange for remuneration to some of the unemployed engineers, etc., etc.
9. Each Institute Section is requested to keep the national committee on economic status of the engineer advised, through national headquarters in New York, as to progress and results obtained. The national committee, in turn, will endeavor to be of such aid as may be feasible.

It is the hope of the board that each Section will proceed, by cooperation with other sections of national societies and local engineering societies, if any, to organize in each community a single engineers' unemployment relief committee in accordance with the plan as outlined in the resolutions. To be effective, this program in behalf of unemployed engineers should be taken up vigorously and at once. Cities already organized in substantial accord with this resolution include Boston, Mass.; Chicago, Ill.; San Francisco, Calif.; and Toledo, Ohio.

In the metropolitan area of New York City, the American Society of Civil Engineers instigated activities to relieve unemployment. The Professional Engineers Committee on Unemployment Relief then was formed on the proposal of the A.S.C.E. that the four Founder Societies form a joint body to cope with the acute situation resulting from the large numbers of persons involved in that section.

The function of this committee is to find employment for professional engineers and to give financial aid to those actually in need. It is headed by H. deB. Parsons as chairman, and functions through an executive committee of which J. P. H. Perry is chairman, a financial committee with H. A. Kidder (F'29) as chairman, and a relief committee under the chairmanship of G. L. Lucas. Headquarters are in the Engineering Societies Building at 29 West 39th Street. Many members of the four engineering societies concerned are giving their personal time to the various phases of activity. Funds are being solicited for immediate relief and members are asked to help locate work for those still unemployed. A mass meeting attended by more than 800 engineers was held November 9 to acquaint members with the details of the plan and to inspire immediate action.

Faraday Centenary Meeting Well Attended

The memory of Michael Faraday was honored at a meeting held in the auditorium of the Engineering Societies Building, New York, N. Y., November 18, 1931. This meeting was under the auspices of the New York Museum of Science and Industry and was attended by about 700 persons.

Frederic B. Pratt, president of the museum, opened the meeting and called upon Dr. F. B. Jewett (F'12) to preside. Addresses were given by Prof. D. C. Jackson (F'12) head of the electrical engineering department of the Massachusetts Institute of Technology and Dr. Elihu Thomson (F'13-HM'28) director of research of the Thomson Laboratories of the General Electric Company. The subject of these addresses was the life and work of Michael Faraday. The meeting was arranged by the Faraday centenary committee of the museum, which consists of F. B. Jewett, chairman, G. F. Kunz, L. F. Loree, F. B. Pratt, C. W. Rice (F'12) C. R. Richards (M'24) M. S. Sloan (F'30) Frank A. Vanderlip, and Felix M. Warburg.

Standards

Mercury Arc Rectifiers

At the October 6th meeting of the A.I.E.E. standards committee, the report of the sectional committee on mercury arc rectifiers was received. This sectional committee, working under the rules of procedure of the American Standards Association and sponsored by the Institute, points out in its report that it appeared unwise to attempt to formulate rigid standards at this time.

After designs become fixed and greater operating experience is obtained, standards of a more rigid character will be made. The sectional committee found it necessary also to depart from the original set scope, and to confine its attention to metal tank rectifiers. There was no evident demand for standards for other types. The standards committee recommended to the board of directors the approval of the Institute as sponsor of the report. This approval was given on October 23, 1931. Upon final approval by the American Standards Association, this standard will become available in pamphlet form. Due notice will be given in a later issue of ELECTRICAL ENGINEERING.

Sound Measurement Committee Authorized

Following the Symposium on Noise presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931, recommendations were made to the board of directors that an Institute committee be appointed to cooperate with existing similar committees of several other organizations to develop uniform and practical standards for noise measurement. The matter was referred to the standards committee and at its October 6th meeting Chairman MacCutcheon was authorized to appoint the necessary contacting committee. Completion of the committee personnel is expected shortly, when work will get under way.

School Lighting Code Under Revision

The Illuminating Engineering Society has just issued in reprint form a revision of the Code of Lighting School Buildings prepared under the joint sponsorship of the Illuminating Engineering Society and the American Institute of Architects and adopted June 16, 1924, as an American standard under the procedure of the American Standards Association.

In this proposed new edition the primary purpose has been to establish criteria of good illumination for the guidance of architects, engineers, school officials, and others interested in the conservation of children's vision and the well-being and efficiency of both pupils and teachers.

This revision is now subject to approval by the sectional committee, the sponsors, and the American Standards Association, after which it will become available in pamphlet form. Inquiries and suggestions should be addressed to American Standards Association, 29 West 39th Street, New York, N. Y.

Engineering Foundation

Progress Discussed at Recent Meeting

The October 22nd, 1931 meeting of The Engineering Foundation has been characterized as one of the most progressive yet held. A study of the present industrial system, as proposed by H. V. Coes of The American Society of Mechanical Engineers, the research activities and procedures of the Founder societies, and a new statement of the policy and program of the Foundation, were the principal subjects of the evening.

Two new members were announced: G. W. Fuller, consulting engineer, New York, N. Y., nominated by the American Society of Civil Engineers to succeed W. H. Burr, resigned; and G. G. Crawford, president of the Jones & Laughlin Steel Corporation, member-at-large, to succeed Alva C. Dinkey (A'97) deceased.

By invitation two members of each Founder society's main research committee discussed with the Foundation board a proposal made to the Foundation by the endowment methods committee of the United Engineering Trustees, for the establishment of a research procedure committee to aid the Foundation in ascertaining the research needs of the Founder societies and in making the best use of available resources for aiding the research activities of these societies. There were present from the civil engineers committee, Chairman C. T. Morris, professor of structural engineering, Ohio State University, Columbus, Ohio, and T. Merriman, chief engineer, Board of Water Supply, New York, N. Y.; from the mining engineers, F. F. Colcord, vice-president U.S.S. Lead Refinery, Inc. and F. E. Pierce, consulting engineer, New York, N. Y.; from the mechanical engineers, A. D. Bailey, superintendent of generating stations, Commonwealth Edison Company, Chicago, Ill., W. H. Fulweiler, chemical engineer, United Gas Improvement Company, Philadelphia, Pa., and C. B. Le Page, secretary of the committee; from the electrical engineers, H. D. Arnold (F'29) director of research, Bell Telephone Laboratories, New York, N. Y., and L. W. Chubb (F'21) director of Westinghouse Research Laboratories, Pittsburgh, Pa.

Interesting differences in the research policies, needs, methods and activities of the societies were brought out by the members of their respective committees. After discussion, there was endorsed unanimously the proposal for a research procedure committee attached to the Foundation, this committee to include one member from each Founder society annually selected from, or designated by, its main research committee, with two members from the Foundation board. The recommendation has been submitted to the boards of the Founder societies.

American Engineering Council

A.E.C. Plans Unemployment Relief

Plans to mobilize the nation's engineers behind President Hoover's program to end the depression were announced recently by the American Engineering Council. The Council will work with the relief organization already set up under the leadership of W. S. Gifford (A'16) president of the American Telephone and Telegraph Company, with an aim toward not only promoting emergency measures but also toward the development of sound, permanent employment policies throughout American industry.

A national committee has been appointed by the Council to direct the engineering efforts which will be carried out in detail by additional committees being named in each state. F. J. Chesterman (F'22) vice-president and general manager, The Bell Telephone Company of Pennsylvania, Pittsburgh, Pa., has been named chairman of the national committee with other members as follows:

Gen. R. C. Marshall, Jr. (M'19) vice-president in charge, B-W Construction Company, New York, N. Y. (in charge of construction division of the War Department during the World War); E. K. Ruth, American Oak Leather Company, Cincinnati, Ohio; W. R. Webster, Bridgeport Brass Company, Bridgeport, Conn.; and L. W. Wallace, executive secretary, American Engineering Council, Washington, D. C.

In a number of states, committees are already at work under the following chairmen: C. E. Rose (A'27) Little Rock, Ark.; F. C. Carstarphen, Denver, Colo.; Henry Robinson Buck, Hartford, Conn.; R. W. Prince, (M'30) Dist. of Columbia; Melvin Price, Gainesville, Fla.; R. F. Schuchardt (F'12 and past-president) Chicago, Ill.; Frank D. Paine, Ames, Iowa; Carl Schneider, New Orleans La.; Paul Cloke (M'13) Orono, Maine; F. A. Allner (M'14) Baltimore, Md.; J. P. Hallihan, Detroit, Mich.; Paul Doty (M'12) St. Paul, Minn.; W. M. Cobleigh, Bozeman, Mont.; O. J. Ferguson (F'13) Lincoln, Neb.; George W. Cas , Durham, N. H.; C. A. Mees, Charlotte, N. C.; D. C. Henny, Portland, Ore.; F. F. Schauer, Pittsburgh, Pa.; R. W. Herrick (A'28) Providence, R. I.; J. A. McPherson, Greenville, S. C.; Mark Eldredge (M'20) Memphis, Tenn.; George A. Reed, Montpelier, Vt.; E. B. Norris, Blacksburg, Va.; and Joseph Jacobs, Seattle, Wash. Additional state chairmen are: G. M. Butler, Tucson, Ariz.; H. W. Hitchcock (M'27) Los Angeles, Calif.; R. A. Seaton, Manhattan, Kansas; Col. E. M. Stayton, Independence, Mo.; L. J. Bevan, Montclair, N. J.

DEFINITE PLANS MADE

In a recent report by the committee it was stated most emphatically that "the immediate answer for unemployment is jobs; . . . the spreading of man-hours is the most essential expedient for stabilizing employment that can be suggested at the present time; . . . plans should be started immediately. . . toward lightening the consequences of any further or future unemployment." In line with these stipulations, the committee outlined a comprehensive program under which engineers individually and collectively can develop helpful measures of correction by carefully studying the problem in their respective employment areas.

It is planned to place special emphasis on the study of all proposed or active government projects, and to inform the public or take other action to insure construction being carried out properly and expeditiously. Attention will be devoted also to the development of a future plan to assist in stabilizing industry.

Board of A.E.C. Holds Fall Meeting

The fall meeting of the administrative board of the American Engineering Council held in Washington, D. C., October 30-31, 1931, devoted the full two days to a discussion of numerous problems important to the engineering profession. Among these matters, the progress report of the public affairs subcommittee was presented. The committee is of the opinion that there is urgent need for a general survey of conditions surrounding the transportation of persons and of property in interstate commerce. This survey has been proposed by congressional legislation. It is felt that this investigation should be made not by the Interstate Commerce Commission alone but by a body consisting also of men prominent in the government, and federal reserve system, as well as by representatives of railroads and shippers.

The administrative board adopted a policy relative to legislation concerning rivers and harbors, to the effect that legislation on all unapproved projects should be checked and reported to the committee of public affairs which would determine what action should be taken.

The board also voted to form a special committee to consider the intelligent integration of industry with agriculture not only as an emergency measure, but also as a possibility for future advancement.

St. Lawrence Project Reviewed

At its meeting, January 1931, American Engineering Council voted to appoint a committee to review the economic aspects of the report of the Institute of Economics, made by H. G. Moulton, C. S. Morgan, and A. L. Lee and entitled "The St. Lawrence Navigation and Power Project." C. E. Grunsky, Jr. and E. L. Grunsky were selected to undertake this work.

In this latter report which has just been rendered to American Engineering Council, Messrs. Grunsky found a number of instances in which they questioned the conclusions of the authors of the book.

A copy of the report prepared by C. E. Grunsky, Jr. and E. L. Grunsky may be had upon application to American Engineering Council.

Letters to the Editor

Mr. Edison's Greatest Work

To the Editor:

"A filament of carbon of high resistance" enclosed in a vacuum bulb hermetically sealed—the basis of his first demonstration in 1879 and of the foundation patent in 1880—with the collateral central station developments, around these will finally be written the Edison saga, for, regardless of the importance of his other inventions, the development and mastery of electric lighting by incandescence was Mr. Edison's most dramatic and difficult work, and its influence upon the modern electric age his most far-reaching one.

He did not originate the broad idea of parallel circuit distribution, or of getting light from an incandescent filament and enclosing it in a container, or even the use of carbon, but he was without question the creator of that type of construction which made possible his ideals of an individuality of use analogous to that provided in the existing gas, water and steam systems. To that objective he clung with extraordinary tenacity and courage over a long period beset with many failures and innumerable difficulties, and in the face of ridicule and a nearly unanimous opinion that the end he sought was unattainable.

As a juror at the Crystal Palace Exhibition in Suydenham in 1882, and in charge of special tests, I had an exceptional opportunity for first-hand knowledge, and my conclusions were voiced in a report made to the U. S. Navy Department in 1883, in the following words:

"In the matter of making the transmission of light and power a practical success, in bringing it home to every-day domestic economy, Mr. Edison, without doubt, has done more than all others, and while his system is by no means yet perfect it is unquestionably far ahead of the work of anyone else."

Mr. Edison was the apostle of a universal direct-current supply from central stations at moderate potentials, despite the inevitable limitations, and his individual work in the lighting field, which was his main objective, practically reached its climax in the middle '80's, when he announced his intention to develop "a new crop of inventions," and in 1888 resumed work on the phonograph, invented some nine years earlier. A year later his electric enterprises were consolidated in the Edison General Electric Company, with resultant transfer of most of his responsibilities.

But already the great advances of the succeeding decade, collateral indeed but made by other men, had been initiated and were in full swing. The constant speed industrial motor had been adopted by the Edison Companies in 1885, and the pioneer work at Richmond had laid the foundation of the modern electric railway. The advent of the single and multiphase alternating circuit systems of transmission and conversion of energy at high potential had made possible the utilization of water powers, and with the later development of the steam turbine laid the only possible foundation of the great modern power plants. Soon came also multiple unit train control, vital to mass movements by electricity.

Carbon has now been replaced by its predecessor. th metallic filament; the vacuum, although it must first be got, is no longer a continuing essential; the gas lamp has opened new vistas of economy; and the alternating-current system has come into its own. But whatever the developments in the electric art and however wide the departures in practise, the vital fact remains that Mr. Edison established the first real central station for the general distribution of electricity, and his name has become a symbol for fertility of invention and untiring activity, with results which have made the world forever his debtor. He has indeed lighted the world.

Very truly yours,
FRANK J. SPRAGUE (F'12)
(Past-President of the A.I.E.E.
President, Sprague Safety Control
& Signal Corp., New York, N. Y.)

Engineering Progess—1731-1931

To the Editor:

Complying with the Engineering Foundation desire for engineers' comments on the article on "Engineering Progress 1731-1931," I would like to say that I think Martin J. Insull in his contribution in your September issue has brought up a subject of exceptional importance.

All engineers are convinced that engineering knowledge and skill in the aggregate has been of greatest benefit to Mankind. On the other hand, there are some changes which resulted from engineering achievements and their application that produced quite opposite results. Chief amongst these, in my opinion, has been the shrinkage in size and commercial activity of small towns.

There is, I believe, no question that small towns having populations of from 3,000 to 7,500 people form ideal social, political, and industrial units. That many such towns have reduced importance and even less population today (as a result of massing of manufacture in large cities) is painfully evident.

If Mr. Insull and his affiliated interest and several large manufacturing organizations could work together and demonstrate that Mr. Insull is right as to the possibility and practicability of decentralizing much of our congested manufacturing by distributing it into present or new towns of ideal size and location it would, in my opinion, be of tremendous value to all people.

Of course Mr. Insull is right when he says that under present conditions power can be delivered in any desired amount practically anywhere one would care to develop a town. By working with several large manufacturing corporations such towns could be established any desired distance apart. If only five or ten miles apart, much of the extra overhead expense of superintendence of a small plant need not be appreciably more than in larger plants, for many of their superintendents easily could take care of four or five small plants so located if they all belonged to one corporation. By having in each town plants belonging to two or more corporations the diversified industry that is so desirable would exist in each.

In many cases, by such cooperative effort, old towns could be brought back and above their old standing; but my recommendation would be to build in most cases entirely new and modern towns. If skill were used in finding the best and most attractive locations they could be developed into something far more attractive than the present average town.

When one sees the immense difference between the average small town and the few ideal towns we now have (for instance Dalton, Mass. as built up by the Crane family around their paper mills) it is easy to see that success will be more certain if carried out with "whole cloth."

Assuming the present average power consumption to be about 4 kw. per employee in manufacturing plants, there would be required in a town of 5,000 people, 2,000 of which were working in its factories, some 10,000 kw. of transformer capacity, including domestic requirements. This is enough power to be economical in cost of equipment even if the supply is taken direct from 110-kv. or even 220-kv. transmission lines. If the cost were considered too great at 220 kv., then substations of 20,000-kw. capacity could be used by placing them midway between towns and the power be distributed at from 2.4 to 6.6 kv. to towns on either side.

A little progress has been made already, as we all know, in decentralization of manufacture, but the progress is likely to continue to be slow unless some competent central body skillfully directs the movement.

I think it would be highly desirable therefore, for the Engineering Foundation to appoint a special committee to study Mr. Insull's proposition and show what great things could be accomplished by such an effort.

A committee representing the utilities companies the large manufacturing interests and the architects would seem to be what is needed.

What greater gift could this generation of engineers present to the generations that are to follow, than to arrange so that some ten million or more, who under present practice are doomed to live and work in the congestion of great cities, could work and live in some one of 2,000 such new and delightful small towns.

Very truly yours,
WALTER S. MOODY (A'06, F'12)
(Consulting Engineer, Transformer Departments, General Electric Company, Pittsfield, Mass.)

Personal

Doctor Whitehead to be Awarded Medal

Electrical World Photo

J. B. WHITEHEAD

John Boswell Whitehead (A'00-F'12 and Life Member) professor of electrical engineering and dean of the faculty of engineering, The Johns Hopkins University, Baltimore, Md., is to receive the Elliott Cresson Gold Medal to be awarded by the Franklin Institute on May 18, 1932. This medal is to be conferred "in consideration of his many original investigations of dielectric behavior and allied subjects." *The Journal of the Franklin Institute* gives the basis of this award as follows:

"This medal is awarded for discovery or original research, adding to the sum of human knowledge irrespective of commercial value; leading and practical utilizations of discovery; and invention, methods or products embodying substantial elements or leadership in their respective classes, or unusual skill or perfection in workmanship."

The particular work which lies back of this award is the great amount of research which Doctor Whitehead has carried on during the past eight or ten years in the field of the fundamental properties of dielectrics as related to the behavior of insulating materials. This has covered gaseous ionization in laminated insulation, dielectric absorption in simple and complex materials, properties of liquid dielectrics, particularly the insulating oils, and the relation of these properties to the behavior of impregnated paper as used for high voltage cables. Responsible in a large measure for the advances made is the development of experimental methods for measuring the charge and discharge currents of dielectrics under continuous potential for very short intervals of time following the application of voltage. These continuous voltage measurements have been correlated with alternating measurements so that from the measurements of short time continuous voltage, the behavior of dielectrics under stress may be predicted completely as regards dielectric loss, power factor, and capacitance.

Doctor Whitehead has been active in Institute affairs for many years. He was the founder of the Baltimore Section and for nineteen years served as its chairman. From 1924 to 1928 he was a member of the board of directors of the Institute. He has served as chairman of the electrophysics committee 1912-1916, chairman of the research committee 1923-1927, and at various times as a member of committees on research, electrophysics, electrochemistry, code of principles of professional conduct, education, technical activities, and others. Since its inception he has been identified with the work of the committee on research.

The Institute selected him as its representative on the division of engineering and industrial research of the National Research Council, and as its delegate to the Conference Internationale des Grand Reseaux Electriques, Paris, France, 1927. In connection with the former he served as chairman of the committee on electrical insulation.

Practically every year since 1910 Doctor Whitehead has presented to the Institute one or more papers the aggre-

C. W. RICE

gate of these numbering thirty-two. The Institute publications have been practically the sole medium of publication for his work.

Doctor Whitehead is a Fellow of the American Physical Society, and a Member of the Society for the Promotion of Engineering Education, the National Institute of Social Sciences, the Societe Francaise des Electriciens, and the National Research Council. He was exchange professor to France 1926-1927. Honors awarded him include the Edward Longstreth Medal of the Franklin Institute, 1917, the Triennial Prize of the Institute Elektrotechnique Montefiore Liege, Belgium, 1922 and 1925, and the medal of honor of the University of Nancy, France, 1927.

Calvin W. Rice Honored by A.S.M.E.

A ceremonial to be given prominence on the program of the annual dinner of the American Society of Mechanical Engineers to be held on the evening of Wednesday, December 2, 1931, will be the bestowal of honorary membership in the society upon its secretary Calvin W. Rice (F'12), who for the past twenty-five years has worked with untiring diligence for its advancement both nationally and internationally, professionally, educationally, and civically. His achievements are too well known to require detailed delineation here. For these achievements and because he is considered by his confrérès to typify the finest attributes of the engineer, Doctor Rice has been chosen for honorary membership in this organization. The address of presentation will be made by Dr. Karl T. Compton, president of Massachusetts Institute of Technology, Doctor Rice's alma mater. Dr. William F. Durand (M'20) past-president of the A.S.M.E. will preside over the events of the evening, auspicious in the history of the organization and including the bestowal of four 50-year Badges of Honor upon other veteran members of the Society.

W. H. Sawyer (F'13) recently elected chairman of the executive committee of the Iowa Public Service Company, Sioux City Gas & Electric Company, and the Sioux City Service Company, will devote a portion of his time to active supervision of these properties. but will continue his consultant and sponsorship activities at his New York office, 120 Broadway.

W. N. Clark (A'05) vice-president and general manager of the Southern Colorado Power Company, Pueblo, Colo. has now been elected its president. His vice-presidency dates from 1924, and his work was instrumental in bringing together into one organization four of the leading electric companies in the Cripple Creek mining district.

C. G. Jones (M'18) has been acting as inductive heating engineer for Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., but recently has resigned to become special engineer for the Youngstown Sheet and Tube Company, Youngstown, Ohio.

P. Trombetta (A'21) on the first of October resigned from the research laboratory of the A. O. Smith Corporation of Milwaukee, Wis., to organize The Solenoid Company for the manufacture of electrical machinery and protective devices of divers types.

F. A. Kolster (M'19) formerly chief research engineer for the Federal Telegraph Company, Palo Alto, Calif., removed recently to New York, N. Y., where he will assume new duties with the International Communication Laboratories, Inc.

P. R. Farrow (A'07) who prior to November 15, 1931 was resident engineer for the Kaministiquia Power Company, Ltd., Kakabeka Falls, Ont., Can., now is manager of operations for the Ontario Power Service Corporation, Fraserdale, Ont., Can.

C. E. Baxter (A'22) telegraph and telephone engineer of the New York Central Railroad Company, Grand Central Station, New York, N. Y., has removed to Detroit, Michigan, to continue these services for the company there.

R. H. Ballock (A'25) manufacturers representative of the Central Station Equipment, Tacoma, Wash., entered the government's employ and is senior engineering draftsman in the Navy Department, Bureau of Engineering, Washington D. C.

W. R. Swoish (A'29) who has been salesman in the central station section of the Westinghouse Electric and Manufacturing Company, Buffalo office, has been transferred to the distribution transformer section, Sharon, Pa., as manager.

N. D. Russell (A'24) who has been performing the duties of superintendent of service and technical inspection for Electrical Research Products, Incorporated, Dallas, Texas, now is at Columbus, Ohio, as engineer for this organization.

R. B. Tenney, Jr. (A'10) engineer of the Texas Power and Light Company, Dallas, Texas, recently has become consulting engineer at Dallas for the Power Cost Engineering and Appraisal Corporation, San Antonio, Texas.

M. J. Mallery (A'30) formerly lighting specialist for the Westinghouse Electric and Manufacturing Company, St. Louis, Mo., now has joined the Steam Equipment Company, Memphis, Tennessee, in the office of secretary.

D. S. Nicol (A'14) who heretofore has been associated with Parsons, Klapp, Brinckerhoff & Douglas, Detroit, Mich., entered the educational field as professor of electrical engineering at Nova Scotia Technical College, Halifax, N. S.

Herman Ulanet (A'30) who was superintendent of the Federal Steel Products Company, Newark, N. J., now has been elected president of the George Ulanet Company, engineers and manufacturers in Newark, N. J.

H. E. Hoadley (M'26) who has been serving the Ohio Public Service Company as its superintendent of distribution at Warren, Ohio, recently became engineer for the Empire District Electric Company, at Joplin, Mo.

D. B. Taylor (M'27) previously resident engineer, Albany district, New York Power and Light Corporation, Albany, N. Y., has taken over the superintendency of the Schenectady (N. Y.) district of that company.

S. F. M. Wilde (A'30) who has been occupied as engineer assistant for Johnson & Phillips, Charlton, London, England, recently made new connections with Kennedy & Donkin, Withington, Manchester, Eng.

R. M. Arnold (A'25) who was chief engineer of the radio division, United Air Cleaner Company, Chicago, Ill., now is chief engineer of the radio division of the Grigsby-Grunow Company also of Chicago.

P. F. Meigs (A'31) previously erecting engineer for the Bucyrus Erie Company, South Milwaukee, Wis., now is assistant instructor, department of electrical engineering, University of Kansas, Lawrence, Kans.

S. N. Bose (M'22) inspection engineer, Cazenovia Electric Company, Cazenovia, N. Y. has gone to India to be chief electrical engineer of the Tata Iron & Steel Company, Ltd., at Jamshedpur.

E. deRziha (A'11) heretofore chief engineer of Siemens-Schuckertwerke A. G., Berlin, Germany now is identified with Société Continentale D'Electricité in Alger, North Africa.

R. R. Law (A'31) for the next two years will engage in graduate work at The Harvard Engineering School, Cambridge, Mass. Mr. Law has removed recently from Ames, Ia.

R. M. Bayle (M'21) general engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., now is engineer for the Westinghouse company at Chicago, Ill.

H. F. Jefferson (M'19) removed from Seattle, Wash., recently to become test engineer for the Jackson Bell Company, manufacturers of radios, Los Angeles, Calif.

C. H. Suydam (M'29) planning engineer for the Federal Telegraph Company, Palo Alto, Calif., has been transferred recently to the company's Newark, N. J. office.

J. L. Merrill (M'19) electrical engineer, Philadelphia, Pa., has undertaken a consulting practise in Jackson Heights, Long Island, N. Y.

Obituary

L. T. Robinson Dies November Third

Lewis Taylor Robinson (A'04—F'12) engineer in charge of the general engineering laboratory of the General Electric Company, Schenectady, N. Y., died suddenly at his home in Schenectady, November 3, 1931. His death was attributed to heart attack. He was 63 years old having been born in Springfield, Mass. Mr. Robinson early evidenced a fondness for mechanics, later leaning toward electricity, which was then just coming into practical usage. About that time Lynn became headquarters for the Thomson-Houston Electric Company; two years after the plant was started and when Lewis Robinson was seventeen years old, he was engaged there by E. W. Rice, then plant superintendent. Later Prof. Elihu Thomson took him out of the plant and made him his office assistant. His aptitude made for rapid progress and within a short time he was in charge of the company's standardizing laboratory and the calibration of fine instruments; in 1891, in partnership with G. A. Whitmore, he established a laboratory for electrical testing and the calibration of instruments. This company under the name of Whitmore & Robinson continued until 1893; then Mr. Robinson joined what was then the Schuyler Electric Company, at Middletown, Conn., later acquired by the newly formed General Electric Company. A year later he engaged with the Central Electric Company at Lewisburg, Pa., where he remained until in 1896 he joined the General Electric Company at Schenectady and became one of its chief organizers.

L. T. ROBINSON

For more than twelve years Doctor Robinson has devoted himself generously to Institute activities including active participation in more than thirty-five important committee assignments, several dealing with intersociety and international technical affairs. Three times he served on the Institute's board, twice as vice-president (1916-18, 1920-21) and once as manager (1913-16). Indicative of the wide scope of his active participation, a few of his committee memberships are mentioned: meetings and papers 1910-19 (chairman 1914-18); constitutional revision 1912-13; professional conduct 1912-13; editing 1912-14 (chairman) and 1916-17; standards 1914-27 and 1929 (chairman 1919-20); Edison Medal 1914-16, 1917-30, 1931; Sections 1918-19; coordination 1920-21 (chairman); instruments and measurements 1924-27. He was chairman of the Schenectady, N. Y., Section for the year 1915-16. A great many important subcommittees, particularly those of the standards committee, also received the benefit of Doctor Robinson's advice and counsel, and several important committee and subcommittee reorganizations were engineered by him. As an authorized A.I.E.E. representative he participated in the joint conference which the Founder societies held to organize the American Engineering Council, 1921; the radio standardization conference, 1922; a special committee on international standards, 1926; and the American Standards Association Council, 1929.

Doctor Robinson was the holder of more than thirty patents covering a wide range of electrical apparatus. In 1904 as collaborator in the electrical exhibit of the General Electric Company he received a silver medal awarded by St. Louis exposition. In 1929 Union College (Schenectady, N. Y.) conferred upon him the honorary degree of Doctor of Science as "inventor, engineer, musician." Music was his chief diversion; he promoted, assisted, and sometimes acted as conductor of the General Electric orchestra, and was recognized in musical circles as an artist of noteworthy ability.

He was a member of the Society of Engineers of Eastern New York, the American Physical Society, the National Electric Light Association, the American Association for the Advancement of Science, National Electric Manufacturers' Association, the United States committee of the International Electrotechnical Commission, and the American Standards Association.

George Milton Ogle (M'27) manager of the power and industrial department of the National Electric Power Company, New York, N. Y., and well known for his research work with regard to the effects upon the human system of electric shock, died suddenly October 14, 1931. He was a native of Louisville, Ky., having been born there in 1888. In 1909 he became signal engineer for the Pennsylvania Railroad Company, two years later becoming chief draftsman for Heyward Brothers & Wakefield Company, at Wakefield, Mass.; in three years' time he advanced to the position of superintendent of power and machinery. Then he joined the Edison Electric Illuminating Company of Boston (Mass.) as commercial engineer, removing in 1916 to New York for similar services with the Edison Electric Illuminating Company of Brooklyn (New York). Two years later he became electrical and mechanical superintendent for the Massachusetts Chocolate Company of Boston, Mass., which was making a complete electrification of its Boston plant. As resident engineer of this company, Mr. Ogle then was given entire charge of the mechanical and electrical departments in the erection of a new million-dollar plant at Burlington, Vt. In April 1918, the Westinghouse Electric & Manufacturing Company chose him as general engineer at East Pittsburgh, Pa., where his work was principally in engineering for shipyards. He was appointed chief electrical engineer of the United States Shipping Board Emergency Fleet Corporation, and later held the same position with the Vulcan Iron Works, Inc., Jersey City, N. J. He then became power specialist for the General Electric Company, serving the company in both Schenectady and New York. In 1925 he was made consulting engineer for the General Engineering & Management Corporation, until joining the organization with which he was identified at the time of his death.

Cedric Samuel Anderson (A'21) electrical engineer of the Anaconda Wire & Cable Company, Hastings-on-Hudson, N. Y., and a postgraduate student at Columbia University, dropped dead as he was attending class there on the morning of November 13, 1931. He was 42 years of age, having been born at Boston, Mass., February 16, 1889. While practising engineering, he was studying for his master's degree. Mr. Anderson already held a degree of B.S. in E.E. conferred upon him by Massachusetts Institute of Technology in 1911, which was the year he joined the Telluride Power Company, at Telluride, Colo. Upon the consolidation of several companies to form the Western Colorado Power Company, he was appointed assistant to the general manager, three years later to be chosen as superintendent of the Clark Electric Power Company at Tooele, Utah. In 1919 he left this organization to become sales engineer for West Penn Power Company, Pittsburgh, Pa. soon to be requested to undertake the work of district superintendent; the following year he was promoted to power engineer. His removal to Hastings came subsequent to 1927, and rounded out an experience of twenty years of progressive engineering.

Isaac Newton Lewis (A'07) retired colonel of the United States Army, died suddenly of heart failure the afternoon of November 9, 1931, at Montclair, N. J., where he resided. He was 73 years old, his native city being Uniontown, Pa. Graduating with the West Point class of 1884, he pursued his military training by a course at the Graduate Torpedo School, Willetts Point, which he completed in 1886. Following this he was placed in charge of electrical installations at Fort Wadsworth, subsequently being given charge of the department of electricity, power and power transmission, U.S. Artillery School, Fort Monroe, Va. His inventive genius contributed many devices for both military and civil applications, among them, the Lewis portable, air-cooled machine gun, the first weapon to prove effective against zeppelins. While stationed at Fort Leavenworth, Kans. in 1888 he invented the first successful artillery range and position finder, a device which was accepted immediately by the War Department. He was a member of the American Association for the Advancement of Science, the Union League and the Lawyers Club of New York, the Army and Navy Club of Washington, D. C., the Montclair Athletic Club, and the Colonial Society of Montclair, N. J.

Charles Ernest Long (A'27) general electrician and hydroelectric power plant operator for the Puget Sound Power and Light Company's eastern district, Wenatchee, Wash., met his death October 11, 1931, in connection with a mine accident. Mr. Long, who was 45 years old, was born in Elkhorn, Manitoba, Canada. He served an apprenticeship with the Toronto General Light and Power Company, later starting an electrical contracting business of his own under the firm name of the Davidson Electric Company. In 1915 he enlisted with the 1st Pioneers of the Canadian Expeditionary Forces, electrical division, and in 1917 engaged with the Canadian National Railways, for the superintendency of all electrical construction west of Saskatoon. In 1925 he came to the United States from Alberta, Canada, being employed one year in Seattle as an electrician, and the following year taking up his work with the Puget Sound Light & Power Company Tumwater Canyon plant. Here he was employed until two years ago, when he was transferred to electrician at the Royal Development Company's mine, making his home at Leavenworth, Wash.

Jan D. Otten (A'90) electrical engineer, Amsterdam, Holland, and a Member for Life of the A.I.E.E., died in Amsterdam, September 29, 1931. Doctor Otten retired from active professional practise in 1926, the year in which he received his election to Member for Life. Some of his earliest engineering work was in affiliation with the general European office of the Thomson-Houston International Company, at Hamburg, where he was located at the time he joined the Institute as an Associate in 1890.

Local Meetings

District 1 Executive Committee Convenes at Schenectady

The fall meeting of the executive committee of the Institute's North Eastern District was held in Schenectady, N. Y., October 9, 1931. Present were: *chairman and District vice-president*, I. E. Moultrop (Boston, Mass.); *District secretary*, A. C. Stevens (Schenectady, N. Y.); *Section chairmen*, R. G. Warner (New Haven, Conn.); R. W. Graham (Buffalo, N. Y.); F. R. Finch (Pittsfield, Mass.); Wm. S. Maddocks (Providence, R. I.); F. C. Young (Rochester, N. Y.); R. A. Beekman (Schenectady, N. Y.); C. W. Henderson (Syracuse, N. Y.); *acting Section chairmen*, W. H. Colburn (Boston, Mass.); R. F. Chamberlain (Ithaca, N. Y.); H. A. Maxfield (Worcester, Mass.); *Section vice-chairman*, E. E. Johnson (Schenectady, N. Y.); *Section secretary* W. B. Hall (New Haven, Conn.). Also present by invitation were: *assistant national secretary*, H. H. Henline (New York, N. Y.); *past-vice-president*, H. M. Hobart (Schenectady, N. Y.); *Section committee chairman*, E. S. Lee (Schenectady, N. Y.).

Prof. R. G. Warner was elected to serve on the national nominating committee. J. A. Johnson, at present a director of the Institute, was unanimously nominated for District vice-president. In addition to the District vice-president, District secretary, and chairman of the Branch counselors executive committee, the following were nominated for membership on the District coordinating committee: R. G. Warner (New Haven, Conn.); R. W. Graham (Buffalo, N. Y.); J. P. McCann (Worcester, Mass.); and F. C. Young (Rochester, N. Y.).

After discussing the organization of the committee in charge of the 1932 District meeting at Providence, R. I., a motion was unanimously carried to the effect that the 1933 District meeting be held at Schenectady during the early part of May.

Competition between the students of the Pittsfield and Schenectady Sections and the interest which this competition created among the older as well as the younger men, was cited as increasing the interest in student activities. Various means of aiding students in their activities were discussed; among others was suggested that prizes might be offered for student papers, based on delivery and content. Before adjourning, Past Vice-president H. M. Hobart and Assistant National Secretary H. H. Henline expressed their appreciation of the meeting and commended the members for their activities.

District 5 Executive Committee Meets at Chicago

The annual meeting of the executive committee of the Institute's Great Lakes District was held in the rooms of the Western Society of Engineers, Chicago, Ill., on Monday, October 12, 1931. Present were: *president* and *District chairman*, T. N. Lacy (Detroit, Mich.); *District secretary*, A. G. Dewars (Minneapolis, Minn.); *District treasurer*, K. A. Auty (Chicago, Ill.); *Section chairmen*, F. R. Innes (Chicago, Ill.); J. J. Shoemaker (Detroit, Mich.); E. J. Schaefer (Fort Wayne, Ind.); E. L. Carter (Indianapolis, Ind.); N. H. Blume (Madison, Wis.); C. H. Kreuger (Milwaukee, Wis.); Oscar Gaarden (Minneapolis, Minn.); E. H. Waldo (Urbana, Ill.); *Section secretaries*, O. E. Hauser (Detroit, Mich.); C. M. Summers (Fort Wayne, Ind.); E. G. Thoms (Indianapolis, Ind.); L. F. Wood (Des Moines, Iowa); G. F. Tracy (Madison, Wis.); E. V. Lassen (Milwaukee, Wis.); E. H. Hagensick (St. Paul, Minn.); E. A. Reid (Urbana, Ill.); *acting chairman*, C. L. Sampson (Des Moines, Ia.); *acting secretary*, R. D. Maxson (Chicago, Ill.); *District committee on student activities chairman*, G. C. Knipmeyer (Terre Haute, Ind.) Visitors were: *District convention committee vice-chairman*, F. A. Kartak (Milwaukee, Wis.); and *technical program subcommittee chairman*, J. F. H. Douglas (Milwaukee, Wis.).

K. A. Auty was unanimously reelected as District treasurer. Mr. Auty also was nominated for the post of vice-president of the Institute from the Great Lakes District (No. 5). T. N. Lacy was elected a member of the national nominating committee representing this District in the coming election for Institute president.

In addition to the vice-president, secretary, and chairman of the District committee on student activities, the following were elected to serve on the coordinating committee: C. H. Kreuger (Milwaukee, Wis.); N. H. Blume (Madison, Wis.); F. R. Innes (Chicago, Ill.); and E. V. Lassen (Milwaukee, Wis.). A motion was passed that the past coordinating committee continue to serve as a part of the District convention committee, assisted by the new coordinating committee. The report of the District convention committee was read and a motion was carried inviting the board of directors to meet in Milwaukee during the coming District convention. Reports of Section activities were also made.

Means of increasing the Institute's membership, as well as interest in Section meetings, were discussed. A motion was passed that a tentative program of Section meetings be prepared early in the season and circulated to all other Sections in the District.

Chicago Power Group Holds Season's First Meeting

The first meeting this season of the Chicago Section's Power Group was held October 22, 1931, in the Engineers Building, Chicago, in joint session with the Electrical Section of the Western Society of Engineers.

A brief introductory address by F. R. Innes, chairman of the Section, was followed by a discussion by P. B. Juhnke and A. R. Lake of the Commonwealth Edison Company before an audience of some 160 persons. The subject was "Power System Operation in the Chicago District." Mr. Juhnke dedicated the meeting to Mr. Edison whose early inventions had made the power industry possible; Mr. Lake described in detail some of the actual problems of interconnected system operation, demonstrating with the aid of charts and diagrams the subjects of telemetering, power flow control, frequency control, reserve capacity, etc. A recent case of trouble due to lightning on the overhead lines of the interconnected system was described illustrating the real effectiveness of reserve capacity for preserving continuity of service.

Future Section Meetings

Akron

December 8, 1931—Television, by J. O. Perrine, American Tel. & Tel. Co. Meeting to be held in the auditorium of the Firestone Tire & Rubber Co.

January 12, 1932—X-Ray Inspection of Welds, by Ancel St. John, president, St. John X-Ray Service Corp. Movies: "Story of Steel." Meeting to be held in the auditorium of the Ohio Edison Co.

Chicago

December 2, 1931—Short-Circuit Calculations and Application of Oil Circuit Breakers, by W. C. Hahn, General Electric Co.

January 7, 1932—Control of Noise and Vibration in Station Design, by P. E. Stevens, Byllesby Engineering and Management Corporation.

Cleveland

December 17, 1931—Behind the Scenes, by Dr. Zay Jeffries, metallurgical engineer and consultant; W. L. Enfield, manager, incandescent lamp development laboratory. Both of these speakers are with the General Electric Co. at Nela Park. Joint meeting with the Illuminating Engineering Society.

January 21, 1932—Some Institute Problems, by Dr. C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co.

Dallas

December 21, 1931—Social meeting.

January 18, 1932—General Developments of 1931. This subject will be covered by students of the Southern Methodist University Student Branch.

Detroit-Ann Arbor

December 1, 1931—Subject and speaker to be announced later. Meeting to be held at Detroit Edison Auditorium.

January 19, 1932—Ladies' night.

Lehigh Valley

December 11, 1931—Inspection trip to the central breaker of the Locust Summit District of the Philadelphia & Reading Coal & Iron Co. at 1:30 p. m. Dinner at the Necho Allen Hotel in Pottsville at 6:30 p. m. At 8 p. m. the following papers will be presented:

Electric Power in the Coal Fields and Its Application to Coal Mining, by W. H. Lesser, Penn Anthracite Mining Co.;

Field Tests of Circuit Breakers, by Prof. A. R. Miller, Lehigh University.

Louisville

December 18, 1931—The Engineer's Place in the Sun, by Prof. W. E. Freeman, University of Kentucky, and vice-president, Southern District No. 4, A.I.E.E.

January 22, 1932—Practical Application of Light Sensitive Cells, by J. U. Briesky, research engineer, Westinghouse Elec. & Mfg. Co.

Lynn

December 2, 1931—Ladies' night.

December 16, 1931—Lightning, by K. B. McEachron, General Electric Co.

January 6, 1932—Ladies' night.

January 16, 1932—Inspection trip to Loose Wiles Biscuit Co.

January 20, 1932—Local convention. Subject:—Centrifugal Air Compression.

Pittsburgh

December 8, 1931—Recent Developments in Electrical Research, by Dr. Phillips Thomas, research engineer, Westinghouse Elec. & Mfg. Co.

January 12, 1932—Some Institute Problems, by Dr. C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co.

Seattle

December 15, 1931—Rural Electrification Meeting. Papers by Prof. G. S. Smith, Washington State College; and H. J. Gille, manager, agricultural and industrial development, Puget Sound Power & Light Co. H. V. Carpenter, vice-president, North West District No. 9, A.I.E.E. will give a talk on Institute affairs.

January 19, 1932—Presentation of papers submitted for annual prize competition. Titles and speakers to be announced later.

Vancouver

December 7, 1931—The Design of the Modern Radio Receiver, by V. W. M. Fouracre, Northern Electric Co., Ltd.

January 4, 1932—Subject and speaker to be announced later.

Past Section Meetings

Baltimore

The Canal Situation, by J. F. Stevens, consulting engineer, former chief engineer of the Panama Canal (1905-07). Mr. Stevens discussed the economics of a supplementary route through Nicaragua and pointed out that from all statistics available the Panama Canal is of sufficient capacity to take care of all shipping requirements for years to come. Joint meeting with the A.S.C.E. and A.S.M.E. Sections, and Engineers Club. October 22. Attendance 150.

Chicago

Power System Operation in the Chicago District, by P. B. Juhnke and A. R. Lake, both of the Commonwealth Edison Co. October 22. Attendance 160. (A complete report of this meeting is published in this issue under "Local Meetings" p. 982.)

Cleveland

In the afternoon, members and guests assembled at the dock of the "U.S.S. Akron" where an interesting lecture was given by one of the guides who described the dock and dirigible. Following this lecture, those present went to the laboratories of the Ohio Insulator Company where opportunity was afforded to inspect insulators of recent design. In the evening W. T. Van Orman, Goodyear Zeppelin Corp., spoke on Developments of Lighter-than-Air Craft. A. O. Austin, Ohio Insulator Co., gave a series of demonstration illustrative of new developments in high voltage phenomena. Joint meeting with the Akron Section. Members of the Cleveland Engineering Society invited. October 8. Attendance 376.

The Navigation of the Akron, by Lieut.-Commander C. E. Rosendahl, captain of the "U.S.S. Akron." By the use of motion pictures, the evolution of airship construction was illustrated from that of the first crude ship built by Count Zeppelin to that of the Akron. Joint meeting with the Cleveland Engineering Society and the Akron Section. October 13. Attendance 1,500.

Columbus

Television, Its Fundamental Physical and Psychological Principles, by J. O. Perrine, American Tel. & Tel. Co. This lecture was accompanied by demonstrations of the types of apparatus used in television. October 27. Attendance 154.

Connecticut

The Fundamentals of Radio Broadcasting, by Prof. W. J. Williams, Rensselaer Polytechnic Institute;

The Requirements of Radio Broadcasting on Communication Circuits, by H. W. Sundius, Southern New England Telephone Co. Following these talks there was an inspection of the WTIC studios in the Travelers Building and of the transmitter on Avon Mountain. October 28. Attendance 300.

Dallas

Construction of the Hamilton Dam on the Colorado River in Texas, by F. A. Dale, Emery, Peck & Rockwood Development Co. October 19. Attendance 115.

Denver

Some Thoughts on Waves, by O. B. Blackwell, American Tel. & Tel. Co. Dean H. S. Evans and Prof. R. E. Nyswander, chairman, gave reports of the summer convention held at Asheville, N. C., last June. Joint meeting with the Telephone Pioneers of America and The American Bell Club. October 16. Attendance 75.

Detroit-Ann Arbor

Recent Developments in Electric Heating, by H. J. Hall and G. Coley, both of the Detroit Edison Co. Illustrated by slides. J. J. Shoemaker, chairman, gave a résumé of the District executive committee meeting held in Chicago. October 12. October 20. Attendance 80.

Erie

Development and Uses of the Modern Oscillograph, by A. D. MacAffer, General Electric Co. Many interesting tests made on the oscillograph were shown. October 20. Attendance 75.

Fort Wayne

Contact Potentials and the Theory of Dielectrics, by Dr. Karl Lark-Horovitz, Purdue University. Illustrated with slides and blackboard sketches. October 15. Attendance 75.

Houston

Effect of Wave Form on Operation of Induction Type Protective Relays, by P. H. Robinson, Houston Lighting and Power Co. Dinner preceded the meeting. October 29. Attendance 23.

Indianapolis-Lafayette

The Relation of Frequency and Quality in Communication, by J. L. Wayne and E. R. Moore, Indiana Bell Telephone Co. This talk brought out the importance of frequency requirements in the transmission of speech, music, and pictures. Demonstrations followed. Dinner preceded the meeting. October 16. Attendance 45.

Kansas City

Aims and Activities of the A.I.E.E., by Dean George C. Shaad, University of Kansas, and vice-president, South West District (No. 7) A.I.E.E. October 14. Attendance 54.

Building a Skyscraper, by G. O. Brown, Kansas City Power & Light Co.;

Conditions in Europe, by E. E. Howard, of Ash, Howard, Needles & Tammen;

Conquering the Missouri River, by Robert McDowell, student, A.I.E.E.

India, by Mundadhi Rau, student, A.S.M.E.

Joint meeting with the A.S.M.E. Section and the A.I.E.E. and A.S.M.E. Student Branches at the University of Kansas. November 5. Attendance 200.

Lehigh Valley

Inspection trip to the new hydroelectric project of the Safe Harbor Water Power Corp. October 3. Attendance 212.

Los Angeles

A Picture of Wave Motion, by O. B. Blackwell, American Tel. & Tel. Co. Illustrated with lantern slides. October 6. Attendance 103.

Louisville

Engineering Marching On, by Dean F. Paul Anderson, University of Kentucky. Short talk by Prof. W. E. Freeman, University of Kentucky, and vice-president, Southern District (No. 4,) A.I.E.E. October 30. Attendance 94.

Lynn

Three sound pictures were presented, "An Address by Dr. A. E. Kennelly, past-president of the A.I.E.E.," "Dr. W. D. Coolidge, Research Laboratory, General Electric Co., and his Cathode Ray Tubes," and "Mazda Lamps Preferred," followed by the serving of refreshments and an informal get-together of members present. October 21. Attendance 400.

Madison

Some Unique Electrical Heating Effects, by Prof. Edward Bennett, University of Wisconsin. Demonstrated. L. C. Larson, Section Delegate, gave a brief résumé of the 1931 summer convention held at Asheville, N. C. Dinner preceded the meeting. October 21. Attendance 45.

Memphis

Annual dinner meeting at which the following officers for the year 1931-32 were announced: W. A. Gentry, chairman; F. L. Christenbury, secretary; O. F. Long, treasurer, W. F. Bowld, M. Eldredge, and G. F. Leake, directors. Short talks by M. Eldredge, retiring chairman, W. A. Gentry, chairman, and W. R. Herstein, president, Memphis Chamber of Commerce. October 13. Attendance 40.

Minnesota

Electric Water Heating, by R. R. Herrmann, Northern States Power Co. Dinner preceded the meeting. October 28. Attendance 30.

Nebraska

Some Institute Problems, by Dr. C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Elec. & Mfg. Co. Doctor Skinner showed several reels of motion pictures that he had taken on a recent world tour. Dinner preceded the meeting September 28. Attendance 180.

Niagara Frontier

The X-Ray in Industry, by E. W. Page, General Electric X-Ray Corporation. Illustrated by slides and motion pictures. Dinner in honor of the speaker was held at the Hotel Niagara. October 16. Attendance 85.

Philadelphia

Modern Long Distance Telephone Communication, by A. P. Godsho, Bell Telephone Co. of Pennsylvania. An active discussion followed the presentation of this paper. October 12. Attendance 75.

Pittsburgh

The Modern Engineer, by S. M. Kintner, Westinghouse Electric & Mfg. Co. Joint meeting with the Engineers Society of Western Pennsylvania. October 21. Attendance 140.

Portland

Ariel Hydroelectric Development, by G. Wisting and O. L. LeFever, both of the Northwestern Electric Co. Mr. Wisting spoke on the construction of the Ariel plant and showed slides of pictures taken during that period. Mr. LeFever outlined the electrical and hydraulic features of the development. October 20. Attendance 62.

Inspection trip to the Ariel Hydroelectric Development. October 24. Attendance 45.

Rochester

The Engineer as a Citizen, by Roy V. Wright, managing editor, *Railway Age*, and president, A.S.M.E. Interesting discussion followed the presentation of this paper. Joint meeting with the A.S.M.E. Section and Rochester Engineering Society. October 1. Attendance 128.

St. Louis

Some Institute Problems and the Electrical Industry, by Doctor C. E. Skinner, president of the A.I.E.E., and assistant director of engineering, Westinghouse Electric & Mfg. Co. October 21. Attendance 65.

San Antonio

Army Air Corps Service, by Lieut. E. C. Lynch, instructor at Randolph Field. October 19. Attendance 37.

Saskatchewan

The Theory and Practise of Electrical Surveying, by Prof. T. Alty, University of Saskatchewan. Illustrated by slides. October 16. Attendance 22.

Seattle

The Engineer and the Community, by J. Frank McLaughlin, Puget Sound Power & Light Co. Annual dinner meeting. September 15. Attendance 86.

E. E. Fellows, General Electric Co., outlined problems which confronted the *Seattle Times* when it moved from a d-c. area to an a-c. area. K. L. Howe, Westinghouse Elec. & Mfg. Co., discussed the problem of maintaining the proper temperature of the molten metal in linotype machines. Wallace Quistorff, Puget Sound Power & Light Co., described the power supply arrangements for the *Seattle Times*. The meeting then adjourned to the Times Building for an inspection trip through the plant. October 20. Attendance 76.

Sharon

Simplified Practise and Standardization, by R. E. Hellmund, Westinghouse Elec. & Mfg. Co. November 3. Attendance 95.

Southern Virginia

Friday evening, October 30: Meeting opened with address of welcome by J. H. Berry, chairman. Motion pictures illustrating the four stages of power generation and the turbo-electric driven President Coolidge followed. Prof. W. S. Rodman, University of Virginia, introduced Dr. C. E. Skinner, president of the A.I.E.E. and assistant director of engineering, Westinghouse Electric & Mfg. Co., who spoke on Pioneers and Pioneering. Attendance 139.

Saturday, October 31: Murray J. Idail, manager of engineering, Virginia Public Service Co., described the new Bremo Bluff Plant of that company. An inspection trip to the Bremo Bluff Plant in the afternoon was preceded by luncheon at the William Frank Hotel in Fort Union, Va. Attendance 50.

Spokane

Inspection trip through the Fox Theater. The heating and ventilating system was described by the engineer in charge, and the projection and sound equipment, as well as the lighting effects, were described and demonstrated by operators in the projection booth. October 30. Attendance 55.

Springfield

Carrier Current Street Lighting Control, by Ralph E. Curtis, United Electric Light Co. Illustrated by slides. September 14. Attendance 52.

Welding, by Prof. C. A. Adams, Harvard University. October 13. Attendance 44.

Toledo

Underground Cable Practise, by F. L. Calvert, General Electric Co. October 16. Attendance 45.

Toronto

Waterwheel Governing, by A. Kalin, Woodward Governor Co. Interesting discussion followed. October 9. Attendance 105.

Surge Absorbers, by J. M. Thomson, Ferranti Electric, Ltd. Slides were shown illustrating absorbers used for the protection of meters, cables, and transformers, and the damage done to transformers by surge voltages. October 23. Attendance 111.

Urbana

Aladdin Up-To-Date, by H. D. Sanborn, General Electric Co. Illustrated by lantern slides describing some of the achievements of the research laboratory, with particular reference to the development of the vacuum tube. October 15. Attendance 80.

Business meeting. October 23. Attendance 11.

Utah

Relay Protection, by Felix Guenther, Utah Power & Light Co. Reports of the summer and Pacific Coast conventions were given by Prof. A. LeRoy Taylor, Dr. J. Hugh Hamilton, and Dr. H. T. Plumb. October 12. Attendance 47.

Vancouver

Particulars of Plant and Equipment on the Empress of Japan, by C. Hayden, chief electrician, "Empress of Japan." This meeting was held on board the Empress of Japan and those present inspected the ship at the conclusion of Mr. Hayden's address. October 5. Attendance 100.

The Lois River Power Development, by S. A. Perrot, S. A. Perrot & Co.;

Determination of Plant Efficiency Ruskin Generating Station, by C. W. Colvin, B. C. Electric Railway Co. Ltd. November 3. Attendance 62.

Washington

The Economic Activities of Russia, by Prof. D. O. Kinsman, Catholic University of America. Professor Kinsman described his experiences during a 5,000 mile trip through Russia. Dinner in honor of the speaker preceded the meeting. October 13. Attendance 125.

Worcester

Interesting Effects in Transformer Connections, by Prof. T. H. Morgan, Worcester Polytechnic Institute. October 22. Attendance 40.

Past Branch Meetings

University of Akron

Life of Michael Faraday, by Philip Syracopoulos, student. Frank Marcinkoski elected chairman. October 7. Attendance 19.

The Life of Charles Augustus Coulomb, by Daniel Coorsh, student;

The Principles of Television, by Harmon G. Shively, student. October 28. Attendance 11.

Alabama Polytechnic Institute

Smoker. Prof. W. W. Hill, counselor, gave a talk on the benefits of student enrolment in the Institute. September 17. Attendance 56.

T. E. Curtis, student, gave a report of the operation of the Georgia Power Company's plant near Atlanta. October 8. Attendance 15.

H. H. Altman, student, gave a talk on some of his experiences while employed at the N.B.C. studios in Chicago, Ill. W. H. Mims, chairman, outlined the inspection trip made by the senior students to several of the power plants of the Alabama Power Co. October 28. Attendance 11.

University of Alabama

Election of the following officers: Robert Lake, chairman; Fisher Allen, vice-chairman; Wood-Rowe Purcell, secretary; Irving Rosenblatt, treasurer. October 6. Attendance 11.

Film—"Insulated Wires and Cables." October 19. Attendance 34.

Armour Institute of Technology

Committee appointments announced. Talks were given by the officers to promote interest in the Branch activities. October 16. Attendance 50.

Electron Tubes in Industry, by L. L. Ludwigsen, General Electric Co. October 23. Attendance 60.

University of British Columbia

Lois River Hydroelectric Project, by R. W. Klinck, student;

Line Starting Equipment for Large Synchronous Motors, by L. Williams, student. October 6. Attendance 17.

Mercury Arc Rectifiers, by P. D. Rossiter, student;

Lightning, by H. M. Van Allen, student. October 20. Attendance 14.

Inspection trip to the Seymour Exchange of the B. C. Telephone Co. October 31. Attendance 12.

An Automatic Smoke Tester, by G. E. Barnes, student;

Thyratron Tubes, by J. N. McRae, student.

Film—"The Wizardy of Wireless." November 3. Attendance 28.

Brooklyn Polytechnic Institute

How the Dial Telephone Works, by E. J. Kane. Bell Telephone Laboratories, Inc. Illustrated. October 20. Attendance 32.

California Institute of Technology

Electrical Advertising and Some of Its Applications to Industry, by Mr. Prosser. October 30. Attendance 29.

University of California

The Life of Edison, by Louis Rockholt, student;

Edison as an Inventor, by Harold Wright, student;

Edison as a Personality, by Forrest Taylor, student.

Two films were shown, as follows: "Edison as a Benefactor" and "Edison as He is Today." October 7. Attendance 61.

Amateur Radio, by Clayton Bane, American Radio Relay League;

Relation of the Radio Amateur to the Radio Industry, by A. H. Babcock, Southern Pacific Co.;

Beam Transmission, by Donald Hall, student. Demonstration of the transmitting and receiving of radio messages at 80 meters. October 21. Attendance 81.

Carnegie Institute of Technology

The A.I.E.E. and the Engineer, by Prof. William R. Work;

The Student and the Institute, by Prof. B. C. Dennison;

History of the C.I.T. Student Branch, by Prof. G. M. Porter, counselor. October 14. Attendance 40.

Case School of Applied Science

An Engineer Visits Europe, by Prof. H. B. Dates, counselor;

Electrical Safety Devices, by J. C. Elder, student.

W. J. Lattin, chairman, gave a summary of the activities at the District meeting held in Pittsburgh March 1931. October 22. Attendance 39.

Catholic University of America

Election of the following officers: Ralph Brady, president; Joseph DeBettencourt, vice-president; James Springmann, treasurer; Robert F. Bourne, secretary. Talk by Prof. T. J. MacKavanagh, counselor, on the purpose of the A.I.E.E. and its benefits to the student. October 21. Attendance 38.

University of Cincinnati

Business meeting. October 12. Attendance 3.

Clarkson College of Technology

Summer experiences were outlined by Prof. A. R. Powers, counselor, and H. Beck and O. C. McNairn, students. October 16. Attendance 24.

Colorado State Agricultural College

Prof. H. G. Jordan and Prof. F. L. Poole, counselor, gave talks on the activities of the Institute and the Student Branch. October 26. Attendance 24.

University of Colorado

The Advanced Course in Electrical Engineering at the General Electric Company, by Professor Palmer. October 7. Attendance 50.

The Madden Dam Project, by H. F. McPhail, U. S. Bureau of Reclamation. Illustrated with slides. October 21. Attendance 60.

Carrier Wave Telephone Circuit, by A. S. Anderson, General Electric Co. November 4. Attendance 90.

University of Denver

Cosmic Rays, by W. Overbeck, student;

Apparatus Used on Cosmic Ray Expedition at Summit Lake, by Paul Barth, student. October 13. Attendance 13.

Film—"Life of Thomas A. Edison." October 26. Attendance 23.

Drexel Institute

Radiation, by E. K. Cliver. October 15. Attendance 26.

Automatic Telephone Switching Equipment, by L. W. Temple, Jr., student. Inspection trip to the Radcliff Exchange of the Bell Telephone Co. of Pa. Dinner preceded the meeting. October 29. Attendance 32.

Duke University

Edison's Life, by Mr. Weaver, student;

Many Inventions of Edison, by Mr. Debrunny, student.

Prof. W. J. Seeley, counselor, outlined Edison's accomplishments and told of his acquaintanc with him during the World War. November 4. Attendance 19.

University of Florida

General discussion of activities for the coming year. October 7. Attendance 28.

G. R. Shafto, Graybar Electric Co., spoke on the trend and development of radio broadcasting. October 19. Attendance 60.

Systems of Street Lighting and Control, by Harvey F. Pierce, student;

Story of the Frequencies, by G. D. Beck, instructor. November 2. Attendance 27.

Georgia School of Technology

Film—"Electric Heat in Industry." October 13. Attendance 75.

University of Idaho

Picnic. September 29. Attendance 30.

University of Illinois

Discussion of activities for future meetings. September 23. Attendance 21.

Social gathering and entertainment. September 30. Attendance 150.

Business meeting. October 7. Attendance 65.

Film—"The Benefactor." October 21. Attendance 45.

Iowa State College

Why Electrical Engineers Should be Affiliated with Their Own Professional Organization, by Prof. F. E. Johnson, counselor. October 7. Attendance 288.

Some Aspects of Power and Communication Systems Affecting Inductive Coordination, by Mr. Carl and two assistants, Northwestern Bell Telephone Co. October 28. Attendance 205.

University of Iowa

Election of the following officers: David Marchant, president; Francis Murray, vice-president; Albert Behnke, secretary-treasurer. September 23. Attendance 45.

Superheterodyne Receivers, by Elwin O'Brien, student. September 30. Attendance 43.

Lightning Disturbances to Power Lines, by I. Piercy, student;

Movietone Films, by L. Travis, student. October 7. Attendance 41.

Current Events, by Ralph Spafford, student;

Parallel Operation of A-C. Generators, by John Weland, student. October 21. Attendance 42.

Kansas State College

Election of the following officers: G. E. Cain, president; E. R. Jensen, vice-president; L. R. Schruben and C. L. Brown, secretaries; W. S. Hemker, treasurer; N. J. Kling, assistant treasurer; D. E. West, corresponding secretary.

The Eye, by Dr. Evans. October 1. Attendance 50. (Evening session.)

The program of the afternoon meeting was the same as that presented in the evening. October 1. Attendance 68.

University of Kentucky

A Review of the Life of Edison, by Z. Pigue, student;

The Life of Faraday, by Thompson Bonzo, student. October 28. Attendance 41.

Lafayette College

Election of following officers: Henry H. Jones, chairman; G. D. Hegeman, Jr., secretary-treasurer.

L. J. Conover, counselor, explained the aims and activities of the A.I.E.E. October 22. Attendance 18.

Lehigh University

The Manufacturing and Testing of High Tension Insulators, by L. B. Huntington, Jr., student;

Automotive Electricity, by G. A. Burn, Mack International Motor Truck Corp. October 15. Attendance 70.

Lewis Institute

Prof. F. A. Rogers, counselor, outlined the privileges and advantages of student enrolment in the Institute. Election of the following officers: L. P. Evans, chairman; H. May, secretary-treasurer. October 22. Attendance 43.

Louisiana State University

Election of the following officers: P. W. Stokeley, chairman; B. F. Marx, vice-chairman; E. R. Wilkinson, secretary. October 17. Attendance 20.

University of Louisville

Relays, by C. B. Eldredge, student. Henry K. Friedman elected secretary. October 9. Attendance 21.

Massachusetts Institute of Technology

Inspection trips to the Milk Street Manual Exchange and Toll Center, and Kenmore Commonwealth Automatic Exchange, both of the American Tel. & Tel. Co. October 20. Attendance 21.

The Relation of Engineering Education to Industrial Careers, by R. I. Rees, assistant vice-president, American Tel. & Tel. Co. Moving pictures and dinner followed this address. October 23. Attendance 250.

Michigan College of Mining and Technology

Three films presented, as follows: "The Life of Thomas Edison," "Trip Through General Electric Works at Schenectady," and "Behind the Lines." October 16. Attendance 56.

J. S. Francis, student, outlined a trip he had taken to several industrial plants in Detroit and emphasized the part played by electricity. October 30. Attendance 26.

Michigan State College

E. W. Moore, chairman, outlined the advantages of student enrolment in the A.I.E.E. October 13. Attendance 19.

Life of Thomas A. Edison, by Carl Stringer, student. Accompanied by a film describing the development of the electric lamp. October 27. Attendance 19.

University of Michigan

The Aims and Purposes of the A.I.E.E., by Prof. S. S. Attwood, counselor. Election of the following officers: Gary Muffly, chairman; R. W. Rockefeller, vice-chairman; John M. Lyon, secretary; Z. C. Lansdale, treasurer. October 15. Attendance 46..

Some Aspects of the Thermal Problem in Electrical Design, by C. J. Fechheimer, Westinghouse Elec. & Mfg. Co. October 31. Attendance 85.

School of Engineering of Milwaukee

Election of the following officers: A. Oklund, president; Gale Young, vice-president; Robert Stephenson, secretary; A. Pflieger, treasurer.

Prof. V. M. Murray stressed the advantages of student enrolment in the Institute.

Trends in Engineering Education, by Dr. J. D. Ball. October 14. Attendance 134.

University of Minnesota

Prof. J. H. Kuhlmann, counselor, gave a talk on the purpose, aims, and activities of the A.I.E.E. and the student Branch. October 22. Attendance 16.

Mississippi A. & M. College

Plan and Purpose of the A.I.E.E., by Dean L. L. Patterson, counselor. Committee appointments announced. October 1. Attendance 30.

Film—"The Single Ridge." October 26. Attendance 26.

University of Missouri

Carrier Current Communication Over High Voltage Lines, by J. E. Shepherd, chairman. October 14. Attendance 31.

Montana State College

Report of the Pacific Coast convention by H. T. Lambdin, chairman. October 1. Attendance 126.

The following papers were presented by students:

Tungsten Bows to the Plating Bath, taken from *Scientific American*, presented by Charles Anderson;

Welding Stresses are Relieved in the Electric Furnace, taken from *Electric Journal*, presented by Herbert Archibald;

Saluda Hydroelectric Development (from *Electric Journal*) presented by Harry Beck;

Sales Talk for General Electric Review, by Everett Blanchard;

Airplane Flight Aided by Electricity (from *Electric Journal*) presented by Eric Blannin;

Producing Noises from Power Transformers, by Arthur Buckley;

Whole World Helps Build Electric Generators (from *Journal of Electric Workers and Operators*) presented by Edgar Dolum;

Development of Gaseous Tube (from Electrical Engineering) presented by Leonard Estey. October 8. Attendance 117.

Graduate Training for Engineers, by Dr. James Tryon, Massachusetts Institute of Technology. October 15. Attendance 120.

The Story of Edison's Life, by Wesley Funk, student;

Edison's Achievements, by Armin Hill, student. October 22. Attendance 109.

The following papers were presented by students:

Speed Street Car for Dresden (from *Railway Journal*) presented by Helmer Fallman;

Stabilization of Industry (from *G. E. Review*) presented by Edward Fisher;

Growlers for Armature Testing (from *Electric Journal*) presented by James Garrison;

Free Wheeling Street Cars (from *Electric Traction*) presented by Vern Hankins;

Dampers Installed on Hot 110-Kv. Line (from *Electrical West*) presented by Curtis Hanson;

Cylinder Pressure Indicator (from *Electric Journal*) presented by Edward Hughes;

Biography of Alman B. Strowger, by Roderick MacDonald. October 29. Attendance 115.

Newark College of Engineering

Electrical Show. October 9. Attendance 158.

Demonstration and lecture by S. P. Grace, assistant vice-president, Bell Telephone Laboratories, Inc. October 21. Attendance 200.

Inspection trip to South Amboy power station. October 23. Attendance 32.

Europe — Engineering Observations, by Prof. Paul M. Giesy. November 2. Attendance 31.

University of New Mexico

History and Development of the X-Ray Tube, by A. W. Francis, student;

Theory and Explanation of the X-Ray Tube, by H. Mendenhall, student. October 13. Attendance 20.

General discussion of Branch activities. Martin Zirhut elected vice-chairman. October 15. Attendance 10.

Austin True, chairman, gave a description of the District meeting held at Kansas City. October 28. Attendance 9.

College of the City of New York

General discussion. October 1. Attendance 13.

New York University

The History, Organization, and Activities of the A.I.E.E., by H. H. Henline, assistant national secretary, A.I.E.E. September 29. Attendance 27.

The Life of Michael Faraday, by R. D. Nussbaum, student. October 14. Attendance 16.

North Carolina State College

Purpose and Aims of the A.I.E.E., by G. E. Ritchie, chairman;

Advantages of Membership in the Student Branch, by Professor R. S. Fouraker, counselor. October 6. Attendance 25.

Design and Economics of Distribution Systems, by Mr. Roewe, Carolina Power & Light Co. November 19. Attendance 55.

Setting Poles in Florida with Dynamite, by J. E. Whitehead, student. Film—"The Electric Ship." November 3. Attendance 27.

University of North Carolina

Education by Observation, by Prof. G. T. Schmenning. October 19. Attendance 60.

North Dakota State Agricultural College

Fred Payne elected chairman and Orville Isley, vice-chairman. October 2. Attendance 11.

The State College Engineer, by Rae Taylor, student;

The Student Branch of A.S.M.E., by Leonard Lynstad, student;

The Student Branch of A.I.E.E., by Fred Payne, chairman;

The Importance of Mathematics to Engineering, by Mr. Hartwell, instructor;

Scenes of Constantinople, by Prof. W. E. Smith. Joint meeting with the A.S.M.E. Branch and the Engineers Club. October 8. Attendance 106.

Life of Edison, by Oliver Blecken, student. Film—"The Story of Rail Steel." November 5. Attendance 63.

University of North Dakota

First meeting of the season held to discuss plans for future meetings. September 30. Attendance 15.

Prof. H. F. Rice, counselor, gave a résumé of the summer convention held at Asheville, June 1931. October 14. Attendance 15.

University of Notre Dame

EXPERIENCES IN ENGINEERING WORLD SINCE GRADUATION FROM COLLEGE, by Mr. Moyer, General Electric Co. October 5. Attendance 54.

ELECTRIC LIGHT AND POWER IN THE UNITED STATES, by Mr. Dietrich, Indiana-Michigan Electric Co.;

MERCURY ARC RECTIFIER, by Francis Joseph, student;

LIFE OF MICHAEL FARADAY, by Julian Quinn.

Current news presented by Jack Scanlon. October 19. Attendance 74.

SERVICE INTERRUPTIONS, by W. D. Stamm, Twin Branch Power Plant;

TELEVISION, by William Mitsch, student;

WHY I CHOSE ELECTRICAL ENGINEERING, by Joseph Doherty, student.

Current news presented by Jack Scanlon, student. November 2. Attendance 74.

Ohio State University

Smoker. October 8. Attendance 51.

Ohio University

G. B. Wychoff, chairman, gave a talk on the advantages of student enrolment in the Institute. Charles C. Colombo elected secretary. October 14. Attendance 24.

Oklahoma A. & M. College

MICHAEL FARADAY, by Paul Ratliff, student. October 1. Attendance 19.

JOSEPH HENRY, by Clyde Wyant, student. October 8. Attendance 27.

Prof. A. Naeter, counselor, Paul Ratliff, J. Hutchins, chairman, and V. Smith described the District meeting held in Kansas City in October. October 26. Attendance 26.

Oregon State College

Charles Boyle, Aluminum Company of America, gave a summary of the growth of the aluminum industry during the past 40 years, and pointed out the number of recently found uses for aluminum. The three following films shown: "Blasting a Pre-Cast Dam Into Place," "Construction of the 132-Kv. Line from San Bernardino, Calif., to Hoover Dam," and "Construction of the 110-Kv. Line from Rock Island, Washington, to Skykomish, Washington." October 27. Attendance 77.

University of Pittsburgh

Election of officers as follows: R. A. Hartley, chairman; R. J. Campbell, vice-chairman; J. W. Stirling, Jr., secretary. September 23. Attendance 36.

Professor H. E. Dyche, counselor, outlined the purpose and activities of the A.I.E.E. September 25. Attendance 127.

DEVELOPMENT OF VACUUM TUBES, by R. Kertz, student;

POWER FROM TROPICAL SEAS, by H. S. Long, student. October 1. Attendance 125.

Mr. Goebel, Westinghouse Elec. & Mfg. Co., gave a talk on a Mediterranean cruise and a comparison of European manufacturing methods with those in the United States. October 8. Attendance 125.

FOKKER AIRCRAFT CONSTRUCTION, by W. L. Kaiser, student;

THE ELECTRIC SYSTEM, by L. W. Moline, student. October 15. Attendance 119.

Pratt Institute

Discussion of activities for future meetings. October 15. Attendance 22.

AUTOMATIC CONTROL OF LOAD AND FREQUENCY AS APPLIED TO HYDROELECTRIC STATIONS, by R. Neumann, student. H. P. Miller, of the School of Science and Technology, spoke on the importance of the A.I.E.E. in the engineering profession and the advantages of student enrolment. October 22. Attendance 48.

Purdue University

Prof. C. F. Harding gave a talk on the history and activities of the A.I.E.E. with particular reference to the Student Branches. October 6. Attendance 200.

Rensselaer Polytechnic Institute

Talks on experiences during summer employment were given by seven students. October 13. Attendance 144.

Rice Institute

Film—"Buried Sunshine." October 14. Attendance 17.

Film—"Conowingo." October 28. Attendance 11.

General discussion. November 4. Attendance 27.

Inspection trip. November 6. Attendance 19.

Rose Polytechnic Institute

Election of the following officers: John Montgomery, president; Paul Froeb, secretary-treasurer. October 8. Attendance 18.

Professor C. C. Knipmeyer, counselor, outlined the history, purpose, and benefits of the A.I.E.E. October 21. Attendance 38.

A STUDENT'S ATTITUDE TOWARD HIS WORK, by James Payne, read by Charles MacGillvary, student. October 28. Attendance 39.

Rutgers University

Smoker and organization meeting. Election of officers as follows: Frederick Fisher, president; Floyd Taylor, vice-president; Lucas V. Banta, secretary; Harold Measly, treasurer. September 28. Attendance 27.

University of Santa Clara

APPLICATION OF ALUMINUM TO TRANSMISSION LINE CONSTRUCTION, by Howard Fly, Aluminum Co. of America. Illustrated. Joint meeting with the A.S.M.E. Branch. October 15. Attendance 109.

University of South Carolina

Appointment of executive, meetings and papers, publicity, and membership committees. October 8. Attendance 10.

South Dakota State School of Mines

Harold Jepson elected secretary and Roy Full elected vice-chairman. September 29. Attendance 26.

University of Southern California

Dean P. S. Biegler, chairman, Los Angeles Section, gave a brief survey of the work carried on by the Sections and stressed the importance of students taking an active part in Branch activities. September 16. Attendance 31.

F. G. Philo, Southern California Edison Co., Ltd., gave an illustrated lecture on the development of the present steam plant at Long Beach, Calif. September 23. Attendance 35.

T. M. Blakeslee, Bureau of Water & Power, gave an illustrated talk on the development, design, and uses of the oscillograph, showing the various types of multiple element units. September 30. Attendance 30.

INTERCONNECTIONS BETWEEN SUBSTATIONS AND BETWEEN DIFFERENT POWER COMPANIES, by W. W. Austin, student. October 7. Attendance 25.

INDUSTRIAL APPLICATION OF THE PHOTOELECTRIC CELLS, by Edwin W. Morris, Westinghouse Electric & Mfg. Co. October 14. Attendance 31.

Stanford University

M. R. Jones, Jr., chairman, gave a résumé of the Pacific Coast convention held at Lake Tahoe, in August. October 15. Attendance 30.

Stevens Institute of Technology

Prof. Kenneth S. M. Davidson gave a talk on yacht design. Luncheon served before the meeting. Election of officers as follows: Fernley L. Fuller, chairman; Robert A. Chadburn, secretary. October 30. Attendance 45.

University of Tennessee

THE LARGEST METERED TRANSFORMERS, by E. D. Jones, student. Demonstration of high voltages given by Professor J. G. Tarboux, counselor. October 21. Attendance 40.

Texas A. & M. College

VACUUM TUBES, by C. C. Nash, student. Election of the following officers: R. L. Suggs, chairman; E. Bartel, vice-chairman; G. H. Samuels, secretary-treasurer. October 20. Attendance 45.

Texas Technological College

Atmospheric Electricity, by Charles E. Houston, student. October 15. Attendance 15.

University of Utah

How Does the College Education Pay? by Mr. Huntsman. October 15. Attendance 25.

University of Vermont

Static Electricity, by G. S. Flagg, student. Demonstrated. October 12. Attendance 18.

Virginia Military Institute

The Life of Clerk Maxwell, by J. M. Trossbach, student;

Wind Rotor Generators, by J. B. Taylor, student;

The Economic Side of Public Utilities, by L. B. Jones, student;

The Life of Joseph Henry, by E. L. Kostainsek, student. Prof. S. W. Anderson, counselor, supplemented this paper with some interesting facts concerning, his experiments and his contemporaries. October 24. Attendance 70.

Film—"The Building of the 'U.S.S. Akron,'" November 5. Attendance 94.

Virginia Polytechnic Institute

Insulation of Electrical Apparatus, by S. S. Brown, student. J. V. Burgess, student, gave a report on the Signal Corps of the U.S. Army. October 22. Attendance 38.

Life of Thomas A. Edison, by J. R. Perrine, student;

Research Work in the Electrical Field, by R. P. Hankins, student. October 29. Attendance 43.

Vacuum Tube Millivoltmeter, by W. Richardson, student;

Dial Telephone System, by D. E. Young, student. November 5. Attendance 56.

University of Virginia

Prof. W. S. Rodman, counselor, gave a talk on the history, aims, and purpose of the A.I.E.E. and student enrolment. October 19. Attendance 10.

State College of Washington

Introduction of officers, and report on Pacific Coast Convention. October 1. Attendance 38.

University of Washington

Skagit Project, by Glen H. Smith, City of Seattle, Department of Lighting. Illustrated with slides and motion pictures. October 9. Attendance 20.

The Aspects of Commercial Engineering, by H. M. Gustafson, General Electric Co. October 15. Attendance 24.

Electrical Contracting, by Clifford Johns, student. October 22. Attendance 15.

Telephone Plant, by G. L. Larson, Pacific Telephone & Telegraph Co. October 29. Attendance 24.

Three films shown, as follows: "The Electric Ship," "Beet Sugar Production," and "Conquest of the Cascades." November 5. Attendance 20.

Washington University

Discussion of Branch activities. October 8. Attendance 27.

Business meeting. November 7. Attendance 16.

West Virginia University

The following talks were presented by students:

D-C. Power Transmission, by Kenneth DeMoss;

Bottling Electric Heat, by Morgan Sprigg;

3,600-R.P.M., 60-Cycle, Two-Pole Alternators, by E. L. Engle;

Conowingo Hydroelectric Development, by G. E. Hervey;

Synchronized Films, by V. S. Montieth;

Cylinder Pressure Indicators, by G. L. LeFevre;

Construction of Vacuum Tubes, by R. R. McCue. October 12. Attendance 30.

The following talks were presented by students:

Electrical Resistance Strain Gauge, by S. J. Iaquinta;

Benjamin Garver Lamme, by C. L. Barton, Jr.;

Series Street Lamp Cut-Out, by J. Kayuha;

Testing and Changing Insulators in Service, by P. Skaff;

Lighting System in Detroit City Airport, by D. C. Kennedy. October 19. Attendance 30.

University of Wisconsin

Film—"Glimpses of the Orient." October 6. Attendance 75.

Commercial Engineering, by J. K. Affanasiev, student. October 20. Attendance 55.

University of Wyoming

General discussion of activities for future meetings. October 15. Attendance 12.

The Functioning of the Short Wave Transmitter, by Roy Perkins, student. October 20. Attendance 10.

Life of Edison, by F. W. Wickenkamp, student. Illustrated. G. H. Sechrist, counselor, gave a talk on the activities of the A.I.E.E. November 3. Attendance 23.

Employment Notes

Of the Engineering Societies Employment Service

Men Available

ELECTRICAL ENGINEER, graduate, married, 28, with wide experience in industrial plant, electrical construction and maintenance; railway electrification; power plant design, estimating, and supervisory construction. Experience with electric contractor; cost analysis. Desires position with future. C-4428.

RECENT GRADUATE, age 21, single, citizen, good health, Protestant, B.E.E. degree, drafting and clerical experience, organization work. Would like to locate with a firm dealing with illumination or radio. Location, East. C-9756.

EXECUTIVE-MANAGER, public utility property. Technical education, construction, operating, management. Past six years consultant, executive engineer with foreign utility. Previous ten years with nationally known holding company interests. Available immediately. C-4036.

ELECTRICAL ENGINEER, B.S. in E.E. in cooperative college, age 23, experience in radio tube research, physical laboratory tests on synthetic resinoids, and electrical drafting. Desires position in any part of U.S. C-9978.

DISTRICT SALES MANAGER or manufacturer's agent; experienced engineering representative, desires connection with high grade company that has line of industrial or utility equipment. Eastern location preferred. B-4067.

1931 GRADUATE of five year cooperative school in electrical engineering. E.E. degree, age 23, single. Cooperative experience includes machine shop practise, telephone central office trouble shooting, and experience with large municipal fire alarm system. Desires position with manufacturing concern or public utility. Willing to start at bottom. Location, Middlewest preferred, but elsewhere satisfactory. C-9825.

1931 ELECTRICAL ENGINEERING GRADUATE, Midwest university, 23, single. Three months' experience with large public utility. Desires position with any manufacturing firm or public utility. Best of references. Location, immaterial. C-9984.

OVERHEAD DISTRIBUTION ENGINEER, economic cutting of losses, economic transformer spacing, economic wire size, correct voltage, will more than save your company the cost of my salary. Let me show you how I can make your distribution system more economical and efficient. Twenty years' experience. Speaks Spanish, married. United States preferred. C-2453.

FINANCIAL ENGINEER, Cornell (M.E.-E.E.). Twelve years regulator commission; four with utility holding management corporation; eight months intensive course bond buying department leading insurance company; employed almost four years thereafter on financial and fact-finding investigations by outstanding consulting engineering organization. Desires opportunity New York City. Salary open. C-2953.

GRADUATE OF STEVENS INSTITUTE OF TECHNOLOGY, 1931, in mechanical engineering, age 23, and single. Has had experience in communication, electrical installation, test and maintenance for eight years. Conscientious, practical, and willing to do any sort of engineering work. C-9976.

1931 GRADUATE ELECTRICAL ENGINEER, 29, 3 years' cooperative experience with eastern public utility, 5 years' drafting and tool design experience before beginning college course. Single now, married when permanent position obtained. Desires position offering some contact with engineering work. Available on one week's notice. Location, anywhere. C-9834.

GRADUATE ELECTRICAL ENGINEER, 24, B.S. in E.E. Knowledge of design, construction of indicating instruments, also knowledge of electron tube. Two year cooperative course with Weston Electrical Instrument Corporation, (32 departments including shop, office and engineering work). Three years' industrial work before college. Available immediately. Location, United States, Canada. C-9585.

ELECTRICAL ENGINEER, Stanford University 1929; one year Westinghouse Course, six months' experience in manufacturing plant, development and design; nine months' experience in materials testing laboratory, engineering mechanics section, bureau of standards. Desires position in research work in physics or electrical engineering. Available immediately. C-8618.

GRADUATE ELECTRICAL ENGINEER, 22, single. Five years electrician's helper and electrician, experienced on small lighting plants and water systems, six months as machinist, five months Westinghouse Test covering switchboards, circuit breakers, and detailed apparatus. Desires position relating to power generation and distribution. Location, immaterial. C-9981.

ELECTRICAL ENGINEER, 22, single, 1931 technical graduate desires work. Four summers' operating experience in large paper mill. Will go anywhere, speaks Russian. D-23.

ELECTRICAL ENGINEER, married, age 29, graduate B.S. in E.E. 1925, six years' experience in engineering and drafting work with a prominent engineering firm, thoroughly familiar with power station and substation work, both physical and wiring. Desires position with public utility, or manufacturer of electrical equipment. Available immediately. D-22.

GRADUATE ELECTRICAL ENGINEER, married, 34, G. E. Test, and ten years' experience in the utility field, particularly in engineering and maintenance work of underground distribution systems, including a-c. low voltage networks. Desires position with utility in Middlewest or South with responsibility for design or maintenance of distribution system. C-1191.

ELECTRICAL ENGINEER, single, 1928 graduate, G. E. Test. Some power plant and railway substation installation experience, also qualified as radio operator. Considerable experience with mercury arc rectifiers and automatic switchgear. Would prefer position with consulting engineer, or similar firm. D-13.

GRADUATE ELECTRICAL ENGINEER from northern college of cooperative type; B.S. in E.E., 23, single, Protestant. Considerable machine shop and construction experience, automotive practise; two years in cooperative G. E. Test Course, control equipment. Seeking opportunity in engineering design and development. Location and salary secondary to opportunity. Available short notice. D-36.

ELECTRICAL ENGINEER, 32, single, E.E. graduate 1922. Westinghouse Graduate Student Course including electrical design school. Six years' experience induction motor design. One year industrial sales and two years application work on power house auxiliary electrical equipment. Desires position as design, application or sales engineer. Available immediately. Location, immaterial. C-9947.

GRADUATE ELECTRICAL ENGINEER, 24, single, B.S. in E.E., W.P.I. 1931. Four years' experience in construction; one year's experience in transmission work. Desires work in any electrical engineering field. Available at once. Location, optional. D-45.

ELECTRICAL CONSTRUCTION ENGINEER, graduate Case School of Applied Science 1928, age 27, married. Three and one-half years' experience with large electrical contractor in estimating, design, control work and field supervision. Excellent references. Middlewest location preferred. Available immediately. D-46.

SALES ENGINEER, B.S. in E.E. 1926, 27, single, experienced indicating instruments, utility purchasing department, test department, G. E. meter laboratory, radio sales and service, and retail store management. Desires a connection with a future. Location, immaterial. C-9045.

ELECTRICAL DESIGNING ENGINEER, 36. Six years power plant and preliminary studies, for standardization of indoor and outdoor substations. Six months power construction work. Two years drafting, standardization of factory planning and electrical equipment. Two years inspection and testing, of electrical equipment. Desires connection with consulting engineers. New York City preferred. D-14.

GRADUATE ELECTRICAL ENGINEER, 32, married, nine years' experience, research and development of small electrical devices and instruments. Some experience in the construction of photoelectric tubes, light valves and cathode ray oscillographs. Considerable experience in telephone, radio and railway signaling development. Available on two weeks notice. Location in Chicago preferred. D-58.

GRADUATE ELECTRICAL ENGINEER, 32, single, B.S. degree in E.E. Three years Westinghouse Test, seven years supervising power plants, substations and transmission line construction. Eight years engineering inspector, purchasing, expeditor, resident engineer and writing specifications. Excellent reference. Desires connection with holding company, utility, contractor or manufacturer. Available immediately. Location, immaterial. B-9661.

ENGINEER, Electrical, 37, native American, experience:—industrial mills, drives, lighting, generation, control, protection, underground distribution and some transmission, also design, field work, writing of specifications and calculations. Immediate placement anywhere very urgent; and salary can be easily arranged to the satisfaction of interested party. Willing to learn new phase. B-3172.

ELECTRICAL ENGINEER, Pratt graduate 1928, age 24, single. Three years' telephone experience. Knowledge of long and short haul circuit layout, cable including gas pressure protection, underground circuit and pole line construction, economic studies, estimating and technical photography. Available immediately. Location desired, New York City or vicinity. D-59.

ELECTRICAL ENGINEER, 29. University graduate, degree of B.Sc. 1923. Two years' experience with large management and engineering company in Middlewest. Six years' experience with nationally known electrical manufacturing company in sales, design and production departments. Desires position with manufacturing company. Available on short notice. Location, Eastern states preferred. C-9995.

GRADUATE ELECTRICAL ENGINEER, 1929, single, age 23. Fifteen months as student engineer on G. E. Test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with concern doing consulting or construction work or with utility or manufacturer. Available at once. Location anywhere in United States. C-8028.

1931 GRADUATE of cooperative college. B.S. in E.E. Age 22, single. Six months' experience with manufacturing company, three months of plant maintenance and fifteen months with public utility. Desires position with any manufacturing, utility or engineering concern. Location, immaterial. Available at once. D-40.

M. I. T. GRADUATE ELECTRICAL ENGINEER, 35, married. Six years' industrial and teaching experience in electrical engineering. Several years private research and development work on own initiative. Good ability, integrity, and personality. Desires university teaching position for life work. Location preferred, Middlewest or South. C-2826.

DISTRIBUTION SUPERINTENDENT, age 46. Twelve years' experience as superintendent of distribution and transmission also metering equipment with public utilities in Central and South America. Spanish spoken fluently. Available now, unemployed. B-9642.

UNIVERSITY OF MAINE GRADUATE, B.S. in E.E., 1929, single, 23, 2½ years drafting, railway signaling. Desires any engineering position. Prefers illuminating engineering or teaching. Location, immaterial. Available immediately. D-65.

ELECTRICAL ENGINEER, 38, married. Seventeen years' experience, design, construction and inspection. Qualified to take complete charge of project from preliminary cost analysis work to finish of construction. Last assignment as superintendent of construction on $20,000,000 electrical and mechanical project. Willing to travel. Salary commensurate with position. Available immediately. B-4456.

SALES EXECUTIVE OR ENGINEER: Graduate electrical engineering and business administration. Three and one-half years sales manager with largest concern in its industry. Two years salesman and branch manager. Five years as engineer in public utility field. Has sales promotional and advertising experience. Would also consider purchasing position. Available immediately. B-7954.

ENGINEERING EXECUTIVE, 33, electrical and mechanical graduate, ten years' experience in management, design, construction, production, accounting, and sales, with steel mill, manufacturer, and utility, desires position as chief engineer, works manager, or other executive capacity where a calm, judicial disposition coupled with initiative and aggressiveness will show up in results. C-1297.

ELECTRICAL ENGINEER, 26, single, E.E., two years' public utility experience in construction, distribution, tests of equipment and domestic appliances, and investigations of abnormal conditions. Three years' clerical experience in cost of production. Can handle responsibility. Desires position with public utility, contractor, or manufacturer. References. Location, immaterial. Available immediately. D-47.

ELECTRICAL ENGINEER, E.E. degree, 36, single. Fourteen years' experience public utilities covering valuation work, rate investigations, engineering power plants, substations, transmission lines, including estimates, specifications, design. Experience covers short-circuit studies, stability analysis, investigations of systems for load conditions. Desires position, holding company, operating company, or consulting engineer. Available immediate. C-9570.

ELECTRICAL ENGINEER, 45, married, graduate of Virginia Polytechnic Institute, 1909, B.S. in E.E. Twenty-three years' experience with the Bell System and the International Telephone and Telegraph Corporation in telephone central office equipment design and planning for toll, manual and automatic dial operations. D-48.

ELECTRICAL MECHANICAL ENGINEER, six years' varied design, construction and operating experience on electrified railroads; familiar with valuation work and the design of transmission lines, catenary systems, substations and motive power. American, college graduate, membership in A.S.M.E., A.I.E.E., A.E.R.E.A., A.R.A. Wishes position anywhere with consulting firm, power company, railroad or manufacturer. C-8463.

ELECTRICAL ENGINEER, university graduate, 1910, experience principally in power and light electrical engineering. Desires position offering similar or electric railway experience. Eastern location preferred. B-1923.

TRACTION ENGINEER, 28, single, five years' experience electric traction shops as inspector, since then and at present in charge of service of the Southeast on registers. Two years at Georgia Tech., later graduated in electrical engineering from I. C. S. Was radio operator. Desires position as assistant engineer for electric traction. D-80.

ELECTRICAL-MECHANICAL ENGINEER, graduate of M.I.T. 1919. Competent, resourceful, sincere. Eleven years' experience in telephone circuits, radio retailing and manufacturing, sound equipment design. Desires mechanical development design in similar fields or research work in the application of vacuum tubes to voice or allied channels. C-310.

ELECTRICAL ENGINEER, 30, married, Wisconsin graduate. Two years construction; Westinghouse Course, two years traction engineering; one year appraisals; four years industrial engineering sales development work. Broad knowledge various industries. Special preparation in economics. Desires employment in surveys for financial or commercial firm; investigations; industrial sales; power sales. Location, East, Middlewest. C-3082.

ELECTRICAL ENGINEER, 27, single, experienced in estimating, detailing and layout of substations, transmission, and distribution lines. Also relay testing. Desires position with utility or engineering concern. Location, immaterial. D-89.

GRADUATE COMMUNICATIONS ENGINEER, Purdue, 1930. Age 24, married, experience with the communication problems of railway service. Familiar with Western Union and Bell System service. Also considerable practical work with control equipment, instrument repair and maintenance, and with radio. Location, immaterial. Available on short notice. D-88.

GRADUATE ELECTRICAL ENGINEER, 35, married, 12½ years' experience in low tension equipment and signaling devices. Thoroughly familiar with devices involving time element and controlling apparatus for special applications. Has had designing and manufacturing experience. Location, immaterial. Will accept foreign appointment. Available at once. C-3820.

GRADUATE ELECTRICAL ENGINEER, 33, married, 3 years radio telegraph, 9 years supervision standardization involving: Distribution system materials, construction, generating stations, substations, special equipment, material design, insulation coordination, simplified practises in purchasing, etc. Desires position, sales, distribution, cable; industrial simplified practise; general engineer where practical inventive, developmental ability is required. Prefers Midwest, Southeast. D-44.

DESIGN ENGINEER, native American, age 33, married, technical education, industrial and mining experience, steam and Diesel power plants, auxiliaries, automatic substations, ability to handle men, can write specifications, knowledge of concrete and steel design, air compressor and ventilation installations. Location, Central U.S.A. preferred. C-9849.

SUPERINTENDENT of distribution, 44, married. Graduate Lowell Institute School, Auspices Massachusetts Institute Technology, electrical, industrial management courses. Twenty years' electric utility operating experience; engineering, construction, operation, maintenance of distribution, transmission lines, substations, transportation, first aid, educational works. Has sufficient public utility operating experience to qualify for position of superintendent. C-8411.

1931 GRADUATE IN ELECTRICAL ENGINEERING, B.S., Worcester Polytechnic Institute, single, 22. Desires connection with manufacturing or public utility concern. Location and salary secondary, experience, primary consideration. C-9627.

GRADUATE IN ELECTRICAL ENGINEERING, 1931, age 26, single, has B.S. in E.E. One year of electrical testing with large utility company. One year of electrical drafting of power and control switchboads. Three years' work in practical electricity. Interested in construction and supervision of small plants. Available at once. Location, anywhere. C-9457.

ELECTRICAL ENGINEER, married, university graduate, E.E., M.E. Twenty-two years' experience, designing, construction power plants, substations, transmission, distribution systems, industrial plants. Three years' executive experience charge engineering department large utility syndicate. Three years charge purchasing engineering equipment, foreign interests. Reads, speaks fluently English, German, Russian, Turkish languages. Available immediately. D-84.

ELECTRICAL ENGINEER, 33, married, B.S. E.E. 1921. Ten years automotive maintenance. G. E. Test. Three years designing a-c., d-c. motors, generators, arc welding equipment, control. Three years developing, designing d-c. motors, generators, control for automotive drive. Three years automotive development, maintenance bus, cab company. Interested, electrical automotive, design, maintenance. D-95.

ELECTRICAL ENGINEER, 25, single, B.S. in E.E., 1931, desires work. Interested in manufacture of electrical machinery or radio. D-97.

GRADUATE ELECTRICAL ENGINEER, young, single. Electrical and accounting education. Journeyman electrician experienced in industrial and commercial construction. Also two years with public utility engineering division. Desires position with industrial or contracting concern or with sales organization. Location, foreign or Western U.S., isolated plants satisfactory. D-96.

ELECTRICAL ENGINEER, age 45, technical school graduate, desires position with railway, industrial plant or consulting engineer. Twenty-four years' experience with large street railway and electrical contractor on designing, estimating, construction, and operation, electrical and mechanical. Has had considerable executive responsibility. Conversant with power reports and new projects. Prefer East. C-7202.

ELECTRICAL-MECHANICAL ENGINEER with metallurgical knowledge. College graduate with post-graduate study. Age 30, married. Westinghouse design training. Six years' experience design electrical circuits and mechanical details of control apparatus, specialized in elevator equipment. Interested in alloy welding research. Location, immaterial. Available on short notice. C-9638.

ELECTRICAL ENGINEER, 1931. Slight experience in vacuum tubes, and their application, also with resistor units. Sales experience in radio, telephone and sound systems. Desires position in research, radio, television or sound. Available now. C-5636.

SALES EXECUTIVE ENGINEER, electrical and mechanical training, seven years' sales engineering and executive experience in application of precision equipment to electrical equipment. Would like opportunity to develop sales of mechanical product allied with electrical industry or of electrical nature sold to central stations and industrials. Willing to tackle difficult job. C-5431.

COMMUNICATION ENGINEER, 31, single. Experienced telephone, radio installations; design, development of testing equipment for telephone, radio, sound picture circuits; design, use of semi-full automatic testing circuits to eliminate human element in testing; industrial applications of photoelectric cells, thermionic tubes. Best references as to professional ability, personal integrity. Location immaterial. Available immediately. C-9376.

Membership

Recommended for Transfer

The board of examiners, at its meeting of October 20, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

To Grade of Fellow

Carhart, Frank M., partner, Jackson & Moreland, Boston, Mass.

To Grade of Member

Giese, Raymond C., division plant engr., American Tel. & Tel. Co., Denver, Colo.
Higson, Charles R., supt. of distribution, Utah Pr. & Lt. Co., Salt Lake City, Utah
Hughes, M. C., acting head of elec. engg. dept., Texas A. & M. College, College Station, Texas
Putman, Henry V., manager, transformer engg. dept., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Rode, Norman F., professor of elec. engg., Texas A. & M. College, College Station, Texas
Smith, Robert P., sales engr., Westinghouse Elec. & Mfg. Co., Jacksonville, Fla.
Tabb, Warner T., consulting-technical writing, Gloucester, Va.
Tangie, Alexander A., chief installation inspector, electricity dept., Town Hall, Sydney, N. S. W., Australia

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before December 31, 1931.

Ackerman, C. D., Peerless Bread Machine Co., Sidney, Ohio
Addy, J. G., Jr. (Member) Marc Eidlitz & Son, New York, N. Y.
Andujar, M. K., Philadelphia Business Progress Association, Philadelphia, Pa.
Ashmore, O. B., Dallas Power & Light Co., Dallas, Tex.
Actzine, A. D., Canadian & General Finance Co., Ltd., Toronto, Ont., Can.
Ayers, E. H., General Electric Co., Schenectady, N. Y.
Bassiliades, D., University of Wisconsin, Madison, Wis.
Baum, W. U., Pennsylvania Power & Light Co., Northampton, Pa.
Baumann, G. H., Pennsylvania Railroad, New York, N. Y.
Baumgartner, C. W., Kansas City Pr. & Lt. Co., Kansas City, Mo.
Becker, D. E., Marquette University, Milwaukee, Wis.
Bixby, W. H., University of Michigan, Ann Arbor, Mich.
Book, C. F., Hydro-electric Power Comm. of Ontario, Niagara Falls, Ont., Can.
Boren, J. S., 412 Mercedes Ave., Pasadena, Calif.
Bosman, I. A., Board of Public Works, Holland, Mich.

December 1931

Order Form for Pamphlet Copies of A.I.E.E. Papers

Papers presented prior to September 1931 and upon which articles in this issue are based

Number	Author	Title
☐ 30-144	F. E. Terman, D. E. Chambers and E. H. Fisher	Harmonic Generation by Means of Grid Circuit Distortion
☐ 31-37	C. G. Suits	Studies in Non-Linear Circuits
☐ 31-46	G. Kron	Induction Motor Slot Combinations
☐ 31-53	S. S. Attwood, W. C. Dow and W. Krausnick	Reignition of Metallic A-C. Arcs in Air
☐ 31-54	J. Slepian and A. P. Strom	Arcs in Low-Voltage A-C. Networks
☐ 31-56	H. S. Davis and W. H. Ross	The Philadelphia A-C. Network System
☐ 31-60	Edith Clarke	Simultaneous Faults on Three-Phase Systems
☐ 31-69	C. F. Estwick	The Three-Circuit Transformer
☐ 31-71	P. H. Trickey	Cusps in the Speed-Torque Curves of Induction Motors
☐ 31-72	H. B. Dwight	Proximity Effect in Cable Sheaths
☐ 31-75	E. A. Church	Temperatures in Electric Power Cables Under Variable Loading
☐ 31-90	T. E. Browne, Jr	Extinction of Short A-C. Arcs
☐ 31-96	L. V. Bewley	Transient Oscillations in Distributed Circuits
☐ 31-105	L. A. Kilgore	Calculation of Synchronous Machine Constants
☐ 31-114	S. H. Wright	Determination of Synchronous Machine Constants by Test
☐ 31-115	E. Weber	Field Transients in Magnetic Systems

*Members, Enrolled Students, and subscribers are entitled to one pamphlet copy of any paper in this list if requested within one year from above date. Thereafter a charge of 25 cents per copy will obtain.

Address **Order Department A.I.E.E.**
33 West 39th Street, New York, N. Y.

Name..
Street Address.....................................
City.............................. State...............

☐ **Annual Index for ELECTRICAL ENGINEERING V. 50, 1931**

Published separately in pamphlet form, one copy available upon request to each member or subscriber. The edition of this index will be governed by the number of requests received prior to January 15, 1932; printing and mailing will be deferred until after that date.

Snyder, L., Snyder Electric Shop, Glens Falls, N. Y.
Spittal, W. R., Ferranti, Inc., New York, N. Y.
Stadtfeld, N., Jr., United Elec. Lt. & Pr. Co., New York, N. Y.
Steele, E. S., Royal, Iowa
Steinbrenner, G., 1311 Pierce Ave., Niagara Falls, N. Y.
Stevens, C., Laddonia, Mo.
Stewart, W. E., Nebraska Wesleyan University, Lincoln, Nebr.
Stoddard, H. R., Simplex Wire & Cable Co., Cambridge, Mass.
Stortz, F. A., Jr., General Electric Co., Schenectady, N. Y.
Strawn, T. F., The Home Insurance Co., Quakertown, Pa.
Strommer, E. N., University of Pittsburgh, Pittsburgh, Pa.
Strupp, P. J., R. R. 2, Hartford, Wis.
Suhr, F. W., University of Minnesota, Minneapolis, Minn.
Sylvester, R. A., 417 South Center St., Pottsville, Pa.
Temple, H. P., Wagner Quarries Co., Sandusky, Ohio
Thurm, R. W., Engineering School of Milwaukee, Milwaukee, Wis.
Titter, B. K., Brooklyn Edison Co., Inc., Brooklyn, N. Y.
Troja, J. B., General Electric Co., Schenectady, N. Y.
Umlauf, A., General Electric Co., Schenectady, N. Y.

6 Foreign

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Balaguer, Manuel M., c/o International Tel. & Tel. Co., 67 Broad St., New York, N. Y.
Byrns, William J., 50 Olive Walk, Breezy Pt., Rockaway Point, N. Y.
Cater, C., Sandal, Church Road, Pinner, Eng.
Chilofsky, Joseph, 958 N. 7th St., Philadelphia, Pa.
Cordier, N. A., 126 Chatterton Pkwy., White Plains, N. Y.
Farnlof, Charles G. T., 1318 Laketon Road, Wilkinsburg, Pa.
Garrison, F. G., Internat'l Tel. & Tel. Corp., Buenos Aires, Arg., So. Amer.
Gaylord, R. H., 1814 Virginia Road, Los Angeles, Calif.
Goldsman, Jacob L., 64 Priory Rd., Hampstead, London, Eng.
Kamm, J. Lloyd, 1802 N. Lamar St., Dallas, Texas.
McCulloch, G. B., McVie Caterers, Ltd., Sydney, N. S. W., Australia
Melson, Sydney W., Yeatton Woolrich Road, Abbey Wood, London, S. E. 2, England.
Mountain, C. E., Burma Elec. Supply Co., Mandalay, Burma, India.
Parr, J. C., 245-71st Street, Brooklyn, N. Y.
Pernick, A. S., Westinghouse High Voltage Lab., Trafford, Pa.
Pierson, Walter D., 4710 Locust St., Philadelphia, Pa.
Pistorius, L. H., 193 Jeppe St., Johannesburg, South Africa.
Schrock, John E., 3720 Main St., Lawrence Park, Erie, Pa.
Stempfle, Frederick, 8126 E. Vernor Highway, Detroit, Mich.
Tate, William, Apartado No. 41, Publa, Mexico.
Thakkur, K. B., Box 654, Whiting, Ind.
Voronovsky, T. G., 1162 Waverly Place, Schenectady, N. Y.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during October are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

WHO'S WHO IN ENGINEERING. Edited by W. S. Downs and M. M. Lewis. 3rd ed., 1931. N. Y., Lewis Historical Publ. Co. 1536 pp., 10 x 6 in., cloth, $10.00.——The third edition of this useful work of reference is restricted, in accordance with the recommendations of the advisory committee appointed by the American Engineering Council, to living American engineers who have been practising or teaching engineering for at least ten years. About ten thousand names are included, with authentic brief information regarding professional experience, publications, education, addresses, etc. A geographic index is given.

GEOLOGIC INDEX OF THE PUBLICATIONS OF THE UNITED STATES GEOLOGICAL SURVEY. By G. H. Albertson. Denver, Col., Geological Publ. Co., 1931. 420 pp., 10 x 7 in., leather, $10.00.——Geologists and engineers who have occasion to consult the publications of the United States Geological Survey owe a debt of gratitude to the compiler of this index. It covers all the publications of the Survey and is classified by the latitude and longitude of each locality, the unit being a thirty-minute quadrangle. Key maps make it easy to locate the desired entry, where all the references to the locality will be found.

STARS IN THEIR COURSES. By J. Jeans. N. Y., Macmillan Co.; Cambridge, England, University Press, 1931. 173 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $2.50.——This work, based upon a series of radio talks, is a delightful introduction to modern astronomy written in an informal conversational style by a great astronomer. Starting with a general account of the heavens, the sun's family, the stars, the milky way and the universe as a whole are discussed. Two star maps and a description make possible the identification of the constellations. The book is ideal for the general reader.

1931 SUPPLEMENT TO BOOK OF A.S.T.M. STANDARDS. Philadelphia, American Society for Testing Materials, 1931. 144 pp., 9 x 6 in., paper, $1.50.——This supplement brings up to date the 1930 Book of Standards published by the Association. It contains thirty-two standards, seventeen of which are new and fifteen replacements of former ones. Among them are specifications for alloy-steel, bolting material for high-temperature service; welded wrought-iron pipe; high-test gray-iron castings; aluminum-alloy sheets and castings; hydrated lime; structural clay tile; white and red lead; and bronze powders. Methods are given for testing concrete, brick, pigments, slate, insulating oils, and other materials.

ALTERNATING-CURRENT CIRCUITS. By J. M. Bryant and J. A. Correll. 2nd ed. N. Y., McGraw-Hill Book Co., 1931. 492 pp., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.——An introductory course in the study of a-c. circuits and transmission lines, based upon that given at the University of Texas. The theory of alternating currents first is discussed, and the equations that apply to the various types of circuits developed from the fundamental physical and mathematical principles. In the latter part of the book these principles are applied to polyphase circuits and transmission lines. This edition has been revised, and a new chapter on the consideration of unbalanced polyphase circuits by means of symmetrical phase components has been added.

ELECTROCHEMISTRY. By C. J. Brockman. N. Y., D. Van Nostrand Co., 1931. 348 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.——This book aims to point out the more important applications of the electrical current in chemical manufactures, in a manner that will interest chemists, manufacturers, and plant managers. The general principles are followed by descriptions of the electrometallurgy of the industrial metals, the production of gases and of electrothermal processes. References to sources are numerous.

FRACTIONAL HORSE POWER MOTORS. By A. H. Avery. Lond. & N. Y., Isaac Pitman & Sons, 1931. 152 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, 7s 6d; $2.25.——The essential features of motors with power outputs of less than ½ hp. are presented concisely. Design, constructional features, commutaton and insulation are discussed. Testing and repairing are considered also.

INDUSTRIAL ELECTROCHEMISTRY. By C. L. Mantell. N. Y., McGraw-Hill Book Co., 1931. 528 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $5.00.——Intended both as a textbook in chemical engineering courses and as a work of reference, this book is written from the engineering point of view and stresses the practical aspects of electrochemical processes. Introductory sections on theoretical and technical electrochemistry are followed by sections on electrolytics, electrothermics, and the electrochemistry of gases, in which the industrial uses for winning, plating, refining and melting metals, for manufacturing gases and chemicals, etc., are described. A final section, engineering, discusses materials and power generation.

MESSENTLADUNGSSTRECKEN (Ionenstrecken). By S. Franck. Berlin, J. Springer, 1931. 192 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, 18.50 RM. unbound; 19.50 RM. bound.——This monograph aims to describe the uses of self-maintaining electrical discharges through gases for purposes of measurement and to give exact particulars of the various methods. The widely scattered literature is reviewed quite thoroughly, and full references are given to the original papers. The theory of discharges through gases is presented very briefly, as an introduction to the methods of measurement.

MONOGRAPHS ON PHYSICAL SUBJECTS. N. Y., E. P. Dutton & Co., 1931. Diagrs., charts, tables, 7 x 4 in., cloth, $1.10 each.——(1) Commutator Motor. By F. J. Teago. 80 p. (2) Photochemistry. By D. W. G. Style. 96 p. (3) Thermodyanmics. By A. W. Porter. 96 p. These concise little volumes by men actively engaged in research work on the subjects about which they write, are intended to supply readers of average scientific attainments with compact statements of the modern position in each subject. They are admirably adapted to the needs of those not in contact with active scientific work or engaged on work in related sciences who wish to become quickly conversant with the accepted principles in various fields.

Selected Items From Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Armatures

MEASUREMENTS. An Electrical Method for Determining the Moment of Inertia of a Direct-Current Armature, J. C. Prescott. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 417, Sept. 1931, pp. 1179-1183, 3 figs. Method of determination described requires for its application d-c. quantity meter in addition to voltmeter and ammeter used in method described by G. Kapp; theory and application of this "quantity meter" method are investigated and experimental results are cited to show degree of accuracy that can be obtained.

Cables

LEAD SHEATHING. Lead Covered Cable. *Wire*, vol. 6, no. 10, Oct. 1931, pp. 402-404, 5 figs. Types and uses of lead cable as compiled by Lead Assn.; cable using lead covering; cable sheath metal; telephone cables; power cable; voltages.

SUBMARINE—PROTECTION. Protective Cable Anchoring. *Elec. Rev.*, vol. 109, no. 2802, Aug. 7, 1931, pp. 209-210, 6 figs. Instance of submarine power cables withstanding ship's dragging anchor.

TELEPHONE. British Columbia 1931 Telephone Cable, M. C. Timms. *Telephony*, vol. 101, no. 13, Sept. 26, 1931, pp. 30 and 32, 4 figs. Gutta-percha insulated submarine telephone cable laid by British Columbia Telephone Co., between Mainland and Vancouver Island, Can.; construction identical to that of ocean cables; manufacturing methods.

Condensers

MEASUREMENT. Measurement of Small Capacities, V. V. Sathe and T. S. Rangachari. *Wireless Engr.*, vol. 8, no. 97, Oct. 1931, pp. 543-547, 7 figs. Compact and self-contained d-c. tubes operated arrangement working on principle of substitution is described for measuring capacities from .002 microfarad down to minute capacities such as inter-electrode capacities of tubes.

Conductivity

On the Resistance of Lead to High-Frequency Currents at Superconducting Temperatures, J. C. McLennan, A. C. Burton, A. Pitt, and J. O. Wilhelm. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol. 12, no. 78, Sept. 1931, pp. 707-719, 5 figs. Attempts to find changes in behavior of lead paralleling that of superconductivity for very high frequencies of light waves; in designing experiment highest frequency amenable to accurate measurements, *i. e.*, 10,000 kc. per sec. was chosen; with currents of this frequency phenomenon of superconductivity might occur at lower temperature than 7.2 deg. K., might be only partial, or might not appear at all.

Conduits

CONSTRUCTION. Conduit and Manhole Construction. *Elec. News*, vol. 40, no. 18, Sept. 15, 1931, pp. 41-44, 6 figs. Bell forms of conduit simplify duct-mouth construction; transit-mixed concrete for congested areas; separate trunk line transmission conduit systems where feasible; driven service pipes for customer connections; manholes should not be less than 6 ft. in height; street loading and roof strength precautions; shapes to conform to requirements; precast service boxes; transformer vaults under sidewalk; roof construction; covers and castings; ventilation.

Converters

FREQUENCY. Frequency Changers Also Have Stability Limits, T. G. LeClair and A. J. Krupy. *Elec. World*, vol. 98, no. 13, Sept. 26, 1931, pp. 558-561, 6 figs. Operating conditions indicated that synchronous tie between 25- and 60-cycle systems of Commonwealth Edison Co. might not remain stable under certain disturbances; tie consists only of two 40,000-kw. synchronous frequency changers; tests demonstrate that with both machines under full load loss of one under fault would cause loss of synchronism between systems, although sudden removal of one machine without fault did not.

Corrosion

UNDERGROUND STEEL. The Electrolytic Corrosion of Underground Metallic Structures by Stray Currents, C. M. Longfield. *Instn. Engrs. Australia—Jl.*, vol. 3, no. 8, Aug. 1931, pp. 283-285. Discussion of paper previously indexed from issue of May 1931.

Currents

ALTERNATING—TEXTBOOK. Alternating Currents, C. E. Magnusson. 4th edit., N. Y., McGraw-Hill Book Co., 1931, 685 pp., illus., diagrs., charts, tables, $5.00. Textbook for undergraduate students which discusses fundamental principles of subject and shows their application to industrial problems; changes in edition include rewriting and extension of chapter on instruments, new chapters on systems of units and symbols, on mercury-arc rectifiers and on hot-cathode rectifiers and oscillators, as well as many new diagrams and illustrations. Eng. Soc. Lib., N. Y.

Education

Study of Technical Institutes. *Jl. Eng. Education—Supp.*, vol. 22, no. 1, Sept. 1931, 39 pp., 7 figs. Summary report intended to present in small compass principal findings, conclusions and data of study for wide distribution; contents of bulletin divided into two parts; principal findings and conclusions, and summary of data.

UNITED STATES. Engineering Educational Standards, L. W. Wallace. *Agric. Eng.*, vol. 12, no. 9, Sept. 1931, pp. 343-345, 1 fig. Comments on Dr. W. E. Wickenden's report to Society for Promotion of Engineering Education; each institution should make thorough study of territory it serves and should major on problems peculiar to its area; need for greater standardization of research programs; engineering teachers should be systematically taught how to teach; engineering profession foundation needs to be broadened in direction of social and cultural graces. Before Am. Soc. Agric. Engrs.

Electric Drive

AUTOMOBILE PLANTS. Ford Substitutes A-C. Motors for 27,000 D-C. Units. *Elec. World*, vol. 98, no. 11, Sept. 12, 1931, pp. 452-455, 8 figs. Methods of changing 85,000 hp. in River Rouge plant to alternating from d-c. drives; benefits include conspicuous reduction to maintenance costs and large decrease of energy lost in plant distribution; studies of drive duties reveal opportunities for scaling down motor sizes.

CEMENT KILNS. Methods of Foolproof Control in Cement Works, S. Hopferwieser. *Brown Boveri Rev.*, vol. 18, no. 9, Sept. 1931, pp. 279-287, 18 figs. Complete diagram of connections for electric operation of rotary kiln plant; diagram of electric interlocking connections between drive of rotary kiln and corresponding cooling drum; diagram of connections for remote controlled three-phase double commutator motor of 130 kw.; 1,000-500 r.p.m. driving rotary kiln fan; electrical operation of Lepol rotary kiln plant.

GRINDING MACHINES. Motorization of Modern Grinders, J. W. Harper. *Iron Age*, vol. 128, no. 16, Oct. 15, 1931, pp. 988-991 and 1020-1021, 6 figs. Methods of mounting electric motors on different types of grinding machines; bench and floor-type machines; time ratings of grinder motors; chart showing relation of wheel speed to peripheral speed for grinding wheels of various sizes; high frequencies for high speeds.

Electric Power

ICE PLANTS. Unit Data on Distilled-Water Ice Plant, R. H. Parrish. *Elec. World*, vol. 98, no. 11, Sept. 12, 1931, p. 431. Twelve months' observed data on tons output and kilowatt-hour input on typical South Texas distilled water ice plant with capacity of 90 tons per 24 hr., using can system, may be of value to other similar sized plants as means of comparison.

INDUSTRIAL PLANTS. Industrial Electrification—III, R. H. Silmot. *Elecn.*, vol. 107, no. 2779, Sept. 4, 1931, pp. 304-306, 3 figs. Group drive *versus* individual drive; types and selection of motors; motor driven.

Load Control in Industrial Plants, R. R. Ruggles. *Power Plant Eng.*, vol. 35, no. 18, Sept. 15, 1931, pp. 935-937, 4 figs. Advantageous application of load regulation illustrated by hypothetical case of industrial plant with fluctuating load which purchases power from large central station but also equipped to generate certain portion of its total load requirements; typical wiring diagram of automatic load regulator working on prime mover.

Electric Equipment

EXHIBITIONS. Electrical Machinery and Instrument Design in the Nineteenth Century. *World Power*, vol. 16, no. 93, Sept. 1931, pp. 177-194, 10 figs. Chronological order of exhibits organized by British Electrical & Allied Manufacturers' Assn.; article divided into three parts: Part I dealing with history of development of electricity generator from Pixii's machine in 1831 up to d-c. machines constructed by Crompton, Brush, and between 1880 and 1890 and Ferranti alternator of 1882; Part II describes Instrument Section, and Part III gives brief description of power station model.

OPERATION. Practises That Improve the Operation of Electrical Equipment. *Power*, vol. 74, no. 8, Aug. 25, 1931, pp. 282-284, 4 figs. Modern operating practises that have been adopted to meet requirements for higher degree of reliability and demands for more exact knowledge of equipment performance.

Electrolytes

PUMPS. A Circulating Pump for Liquids, D. R. Barber. *Jl. Sci. Instruments*, vol. 8, no. 6, June 1931, pp. 183-188, 3 figs. Description of non-metal pump designed primarily for circulation of electrolytes; performance of apparatus is discussed from theoretical standpoint, and typical calibration curves obtained with experimental pump are given.

Elevators

ELECTRIC—SIGNAL SYSTEMS. Pre-Register Signal System Stops Elevators Automatically. *Power*, vol. 74, no. 11, Sept. 15, 1931, pp. 391-393, 5 figs. System in which signals to stop are registered in advance by buttons in car and from landings; at proper point in car's travel operator notified by signal to center car switch so that car will stop automatically at landing for which signal was given; equipment design and operation.

OFFICE BUILDINGS. Planning Elevators for Special Service, C. F. Scott. *Eng. News-Rec.*, vol. 107, no. 15, Oct. 8, 1931, pp. 569-571, 6 figs. Description of vertical transportation system of new McGraw-Hill building in New York; nine passenger cars are all 3,500 lb. capacity, in size 7 ft. 4 in. by 6 ft. 4 in., with openings 3 ft. 8 in. wide; high rise cars, running at 800 ft. per min., are equipped with automatic control; low-rise passenger cars, running at 600 ft. per min., are equipped for manual operation, with automatic leveling; smooth operation is obtained through perfected control and extra heavy guide rails; details of pliotron floor leveling mechanism.

Engineering Writing

Technical Writing, T. A. Rickard. 3rd edit., N. Y., John Wiley & Sons, 1931, 337 pp., $2.00. Interest in correct speech has become much more wide-spread since author's book first appeared in 1919, and many textbooks have appeared since that date; his work still remains, however, one of most readable and best guides to engineer who wishes to improve his power of expression; new edition, prepared for American Institute of Mining and Metallurgical Engineers, differs from second edition only in sundry small corrections. Eng. Soc. Lib., N. Y.

Engineers

UNITED STATES. Who's Who in Engineering, edited by W. S. Downs and M. M. Lewis. 3rd edit., 1931, N. Y., Lewis Historical

Publ. Co., 1536 pp., $10.00. Edition is restricted, in accordance with recommendations of advisory committee appointed by American Engineering Council, to living American engineers who have been practising or teaching engineering for at least 10 years; about 10,000 names are included, with authentic brief information regarding professional experience, publications; education, addresses, etc.; geographic index is given. Eng. Soc. Lib., N. Y.

Furnaces

ANNEALING. Annealing and Cleaning Strip Steel for Cold-Rolling. *Iron Age*, vol. 128, no. 16, Oct. 15, 1931, pp. 1000-1003, 4 figs. Layout and operation of electric furnaces at Cuyahoga works of American Steel & Wire Co.; 24 bell type furnaces of 90- to 100-kw. capacity each; operated on three-phase, 220-volt, 60-cycle current; artificial atmosphere; continuous cleaner with various new features in connection with take-up frame.

FOUNDRY. Electric Furnace Developments in Foundries, A. E. Greene. *West Machy. World*, vol. 22, no. 9, Sept. 1931, pp. 424-427, 5 figs. Change from crucible melting furnace to electric furnace; typical furnace installations for economical production of steel and cast iron.

GASES. Principles and Some Practical Applications of Electric Furnaces with Atmospheric Control, A. N. Otis. *Iron and Steel Engr.*, vol. 8, no. 8, Aug. 1931, pp. 352-359 and (discussion) 359, 14 figs. Apparatus for reforming hydrocarbon gases, such as butane, illuminating gas or natural gas into gas consisting largely of free hydrogen, for dissociating ammonia into hydrogen and nitrogen; cost of gases by various methods of procurement; dissociation pressure in atmospheres for iron oxide; hood furnaces for bright-annealing; elevator type furnaces; tunnel type counterflow furnace for heating and cooling in atmosphere of electrolene. Before Am. Iron and Steel Elec. Engrs.

Fuses

The Pressures Produced on Blowing Electric Fuse Links: The Effect of the Surrounding Atmosphere, G. Allsop and P. B. Smith. *Safety in Mines Research Board—Paper*, no. 67, 1931, 19 pp., 1 fig. Fuse links of tinned copper wire have been blown by currents ranging from minimum fusing current to medium overload current at 200 volts d-c. in closed rectangular vessel of 54.0 cu. in. capacity; vessel was thermally and electrically insulated evacuated and filled with gas at known pressure; gases used were: air, oxygen, nitrogen, hydrogen, chlorine, carbon dioxide and argon under atmospheric and other pressures; oscillograms and pressure records were taken during each experiment.

Generators

ALTERNATING CURRENT. Armature Reaction in Salient-Pole Alternators, W. H. Ingram. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol. 12, no. 78, Sept. 1931, pp. 690-707, 11 figs. Theory of alternator as self-modulating dynamical system is outlined; fundamental in it is a family of field magnetomotive and electromotive force characteristics, of which rotor position coordinate is parameter.

WATERWHEEL. Umbrella-Type Generators Reduce Hydro Plant Costs, H. B. Crandall. *Power*, vol. 74, no. 10, Sept. 8, 1931, pp. 358-359, 4 figs. Construction of umbrella-type slow-speed vertical-shaft waterwheel generator and space requirements; comparison with machines of usual design; advantages and disadvantages of various designs of waterwheel generators.

Heating

BUILDINGS. The Electrical Heating of Buildings, R. Grierson. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 417, Sept. 1931, pp. 1045-1090 and (discussion) 1091-1116, 21 figs. Types of electric warming equipment; general details and considerations, *i. e.*, measurement of comfort, physiological, hygienic, architectural and decorative aspect; ventilation; high-temperature *vs.* low-temperature radiating surfaces; continuous *vs.* intermittent heating, etc.; information as actual installations, etc., and bibliography given in 11 appendixes.

RAILROAD BUILDINGS. Reading Installs Thermal-Storage Electric Heating System. *Ry. Elec. Engr*, vol. 22, no. 9, Sept. 1931, pp. 239-240, 2 figs. Unique heating plant used in power dispatcher's building on electrified territory at Philadelphia.

Hydroelectric

PUMPED STORAGE. Waeggital Pumped-Storage Hydro-Electric Scheme. *Engineering*, vol. 132, no. 3425, Sept. 4, 1931, pp. 292-294, 4 figs. Power scheme near Zurich has annual output of 110,000 kw-hr. generated in two stations mainly during winter months; dam closing gorge is of solid gravity type, 363 ft. high by 515 ft. long; pressure tunnel of circular cross-section and 12-ft. internal diam. is capable of carrying 1,160 cu. ft. of water per sec.; Rempen power station has four vertical-shaft Francis-type spiral turbines, each with output of 22,500 hp. at speed of 500 r.p.m.; Siebnen station contains four turbines of same type with outputs of 14,750 to 17,500 hp. at 500 r.p.m.

Insulation

BUILDINGS. Control of Heat, Light and Sound in Modern Buildings, E. C. Rack. *Heat., Piping and Air Conditioning*, vol. 3, no. 9, Sept. 1931, pp. 734-740, 6 figs. Use of insulation for controlling heat, light and sound in modern plants and buildings has developed rapidly within past few years; practical discussion of utilization of insulation of modern buildings; economical thickness of insulation; research and materials for future.

Insulating Materials

STRENGTH. System Insulation Strengths, S. A. Stigant. *Elec. Rev.*, vol. 109, no. 2808, Sept. 18, 1931, pp. 425-426, 5 figs. Introduction to study of coordination of insulation strengths of electrical transmission systems.

Insulators

SUPPORTS. Simpler Supports for Pin Type Insulators. *Elec. Times*, vol. 80, no. 2082, Sept. 17, 1931, p. 431, 2 figs. Eradication of inherent disabilities of existing forms of pole top equipment is aimed at in new tubular system described below.

Lamps

GLOW—VOLTAGE. Now Low Voltage for Tube Lighting, E. Clute. *Am. Arch.*, vol. 140, no. 2600, Oct. 1931, pp. 42, 64 and 66, 6 figs. Revolutionary improvements in production of light by glass tubes filled with rare gases have made it adaptable to architect's requirements as never before; most important of all is recent practical development of low voltage tubes; some of applications and possibilities illustrated.

INCANDESCENT—BURN-OUTS. Calculating Lamp Burn-Out, H. H. Webb. *Elec. World*, vol. 98, no. 12, Sept. 19, 1931, p. 505, 1 fig. Simple formula for calculating normal rate of burn-out of lamps.

ULTRA-VIOLET. The Problem of the Definition and Measurement of the Useful Radiation of Ultra-violet Lamps, C. H. Sharp and W. F. Little. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 7, Sept. 1931, pp. 727-737 and (discussion) 737-743, 2 figs. Most of methods for measuring on basis of erythemal effect are approximate in character and in generality of cases do not give sufficiently comparable results; need for coordination in this field of measurement is pointed out and for establishment of standards both in form of standard methods and physical standards of erythemal radiation; second part reviews most commonly employed physical methods of measurement.

Light and Lighting

Visual Efficiency in Quiet and Noisy Workplaces, M. Luckiesh. *Elec. World*, vol. 98, no. 11, Sept. 12, 1931, pp. 472-473. Results of experiment in which rate of performing exacting visual work was measured in quiet room and in room in which several 10-kw. motor-generator sets were operated.

ULTRA-VIOLET. Industrial Uses of Ultra-violet, E. E. Free and C. C. Clark. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 7, Sept. 1931, pp. 744-755. Summary of industrial applications of ultra-violet under five main headings, each of which is discussed in detail with respect to previous accomplishments and probable future use; need of some simple, reliable means of measuring ultra-violet is stressed and plea made for sources of ultra-violet radiation more intense and more nearly monochromatic than those now available.

STREET. The Street Lighting Requirements of Different Types of Street, J. F. Colquhoun and W. S. Stiles. *Surveyor*, vol. 80, no. 2068, Sept. 11, 1931, pp. 255-256. Requirements which must be considered in lighting different types of streets: revealing power, attractiveness by night, attractiveness by day; dependence of these requirements on brightness level, diversity characteristics of source, etc.; disability and discomfort glare; spectacular lighting. Before Int. Illum. Congress.

Loud Speakers

DESIGN. Dynamic Loudspeaker Design—II, J. E. Goeth. *Electronics*, vol. 3, no. 3, Sept. 1931, pp. 112-113 and 130, 3 figs. Actual computation for typical case is given; data calculated are compiled in table form.

Magnetism

Influence of Hydrostatic Pressure on the Critical Temperature of Magnetization for Iron and Other Materials, L. H. Adams and J. W. Green. *Terrestrial Magnetism and Atmospheric Electricity*, vol. 36, no. 3, Sept. 1931, pp. 161-169, 5 figs. Tests in order to determine whether or not temperature at which iron and other ferromagnetic substances pass from magnetic to non-magnetic state is affected by increase of pressure; specimens of materials investigated were made up as core of miniature transformer or induction-unit, and placed in electrically heated pressure-bomb; six-volt alternating-current was supplied.

Manometers

IONIZATION. A New Design of an Ionization Manometer, E. K. Jaycox and H. W. Weinhart. *Rev. Sci. Instruments*, vol. 2, no. 7, July 1931, pp. 401-411, 11 figs. Vacuum gage described has been developed for measuring pressure of residual gas in highly exhausted experimental tubes used in study of thermionic and photoelectric phenomena at pressures of order of 0.00000001 mm. mercury or lower.

Measurements

A Resistor for the Measurement of Large Direct Currents, E. H. Rayner. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 417, Sept. 1931, pp. 1155-1159, 2 figs. Serious uncertainties in effective value of low resistances for measurement of large currents may be caused by variations of current distribution at their terminals; temperature-rise is also important cause of variation; application of principles for reduction of these errors has been basis of design of resistor of 20 microhms, which has been found satisfactory as reference standard for measurement of currents up to 25,000 amperes.

Metering

REMOTE. Remote Metering System Calibrated Quickly, U. Davis. *Elec. World*, vol. 98, no. 11, Sept. 12, 1931, p. 458, 1 fig. Impulse remote metering system instruments can be checked from load dispatcher's office of Commonwealth Edison Co.; diagram showing 25-cycle part of system.

Microphones

CALIBRATION. The Calibration of Microphones, H. F. Olson and S. Goldman. *Electronics*, vol. 3, no. 3, Sept. 1931, pp. 106-108 and 130, 8 figs. Methods for calibrating various types of microphones including Rayleigh disk, actuator method and thermophone method; comparative curves are given for different microphones.

Motors

BRAKING. Dynamic Braking *versus* Plugging as a Means of Accurate Stopping, P. McShane. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, pp. 516-517, 4 figs. When accurate stopping is essential function of motor aplication, shunt-wound motor, because of its characteristics, is generally used; two methods are used to bring motor to stop, dynamic braking and plugging; simple discussion of both methods, their applications and advantages.

INDUCTION—CIRCLE DIAGRAM. The Circle Diagram of the Polyphase Induction Motor, C. C. Hawkins. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 417, Sept. 1931, pp. 1149-1154, 3 figs. Values of radius and coordinates of center of circle diagram of polyphase induction motor are determined algebraically in form covering not only ordinarily accepted equivalent network, but also more accurate equivalent network in which iron losses for stator and rotor are represented separately.

STARTING. A Combined Motor Starting and Power Factor Correcting Panel. *Engineer*, vol. 152, no. 3948, Sept. 11, 1931, pp. 276-277, 1 fig. Electrical Construction Co. has introduced motor-starting panel, in which all necessary gear for starting, protecting and improving power factor of squirrel-cage machine is contained.

SYNCHRONOUS. Emergency Full-Voltage Starting of Synchronous Motors, O. C. Nelson. *Power*, vol. 24, no. 11, Sept. 15, 1931, p. 399. Automatic emergency full-voltage starting accomplished by balanced-frequency relay; practical discussion of operating features.

Fans Cool Totally Inclosed Synchronous Motors, C. C. Shutt. *Power*, vol. 74, no. 11, Sept. 15, 1931, pp. 396-397, 4 figs. Synchronous motors of 250-hp. rating have been built that are totally inclosed and cooled by external and internal fans for use in severe atmospheric conditions and to operate at 5,000-ft. altitude; motor design and construction.

SYNCHRONOUS—BRAKING. Synchronous Motors Stopped in Three Revolutions, A. S. Rufsvold. *Elec. World*, vol. 98, no. 13, Sept. 26, 1931, pp. 556-557, 2 figs. 400 hp. motor stopped from 450 r.p.m. to rest in 1.25 sec. by allowing armature current only half inrush value at starting; this meets emergency stop conditions, eliminates coasting time of heavy equipment and is applicable to bandsaws, rolls and intermittent operations.

Networks

INTERCONNECTED. The Economic Value of Major System Interconnections, N. E. Funk. *Jl. Franklin Inst.*, vol. 212, no. 2, Aug. 1931, pp. 171-208, 24 figs. Table of power input, loss and delivery of 20 sections, 1,000-mile transmission line; why interconnections between power systems are desirable; details of 220-kv. interconnection of Pennsylvania Power & Light Co., Public Service Electric & Gas Co., and Philadelphia Electric Co.; details are given.

PROTECTION. Protecting A Medium-Voltage Network, J. S. Parsons. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, pp. 520-525, 5 figs. Proper operation of primary a-c. network depends upon satisfactory protective system; plan outlined makes possible adequate relaying, using only well-known and dependable equipment.

Oscillographs

CATHODE-RAY. A Method of Obtaining a Linear Time Axis for a Cathode Ray Oscillograph, A. L. Samuel. *Rev. Sci. Instruments*, vol. 2, no. 9, Sept. 1931, pp. 532-540, 5 figs. Usefulness of cathode-ray oscillograph tube of type of Western Electric no. 224-B is enhanced by any circuit that will provide linear time axis; one method used in Bell Telephone Laboratories employs hot-cathode three-element gas-filled tube in usual "sweep" circuit; this method possesses advantages in reproducibility, ease of control and synchronization; brief description of tube is given together with simple analysis of behavior of circuit. Bibliography.

Photoelectric

CALCULATING MACHINES. A Photoelectric Integraph, T. S. Gray. *Jl. Franklin Inst.*, vol. 212, no. 1, July 1931, pp. 77-102, 12 figs. Machine for purpose of facilitating mathematical solution of problems requiring evaluation of integral in which integrand involves variable parameter is described in this article; it involves use of optical system in which transmission of light is limited in definite manner by apertures having shape of area under curves representing mathematical functions; accuracy of machine itself is from 2 to 5 per cent.

Photoelectric Cells

Photocell Theory and Practise, V. K. Zworykin. *Jl. Franklin Inst.*, vol. 212, no. 1, July 1931, pp. 1-42, 33 figs. Methods of preparation of cell; application in motion pictures television. Simplicity Extends Light-Control Possibilities. *Radio Eng.*, vol. 11, no. 9, Sept. 1931, pp. 21-22, 3 figs.; see also *Radio Industries*, vol. 6, no. 5, Sept. 1931, pp. 166-167, 3 figs. Burgess Radiovisor Bridge new light sensitive cell and simplified associated apparatus, introduced to engineers and experimenters.

COLORIMETRY. The Applicability of Photoelectric Cells to Colorimetry, H. E. Ives and E. F. Kingsbury. *Optical Soc. Am.—Jl.*, vol. 21, no. 9, Sept. 1931, pp. 541-563, 18 figs. Critical consideration of requirements for precision physical colorimeter, and estimation in light of experimental data on new types of photoelectric cells, as to what degree requirements for physical colorimetry may be met at present time; paper is very specially limited to problems of precision color measurement.

Photometers

DAYLIGHT. A Daylight Factor Integrator, H. C. H. Townend. *Jl. Sci. Instruments*, vol. 8, no. 6, June 1931, pp. 177-183, 5 figs. Instrument determines mechanically illumination at point on horizontal surface due to direct light from sky visible at that point; instrument is set up at point, and telescope incorporated in it is made to traverse boundary of visible sky; daylight factor is read off from small integrating wheel.

Photometry

A Method of Measuring the Integrated Light from Short Flashes of High Intensity, L. R. Koller. *Rev. Sci. Instruments*, vol. 2, no. 9, Sept. 1931, pp. 551-553, 1 fig. In course of some tests of flashing beacons for airports it was necessary to measure integrated light from flashes of high intensity but of very short duration; for this purpose circuit using photoelectric tube and thyratron was developed by means of which measurements could be made with great ease to within accuracy of about 10 per cent.

Power Industry

GOVERNMENT CONTROL. Governor Takes Firm Stand Against Government Ownership, A. C. Ritchie. *Elec. World*, vol. 98, no. 13, Sept. 26, 1931, pp. 540-542. Government ownership of power industry would make us political slaves of federal government; state regulation suitably strengthened where it is lacking will solve all problems better than any form of state ownership. Before Am. Bar Assn.

Power Plants

ELECTRIC DRIVE. Large and Small Motors in the Modern Industrial Steam Power Plant, E. A. Murray. *Eng. and Finance*, vol. 25, nos. 2 and 3, Aug. 1931, pp. 29-30 and 38, and Sept., pp. 48 and 57. Specific applications boiler feed pump; circulating pumps; hot-well pumps; forced and induced draft fans; stokers; pulverized coal feeders; pulverizer mills; clinker grinders.

NATURAL GAS. The World's Largest Industrial Consumer, R. M. Bauer. *West. Gas*, vol. 7, no. 5, May 1931, pp. 42-44 and 100, 6 figs. Description of Southern California Edison Co.'s Long Beach steam plant which burns natural gas in huge quantities to supply light and power needs of Southern California; article is non-technical in treatment, laying particular stress upon burner design and gas usage.

Radio

AIRPLANES. Radio on Dutch Air Lines Insures Safety, L. Bruchiss. *Radio Industries*, vol. 6, no. 5, Sept. 1931, pp. 168-169, 4 figs. As example of foreign radio in aircraft, air routes of K. L. M., Royal Dutch Air Lines are taken; began operations in 1920, and may be considered as hub of continental air traffic; since establishment of 10,000 mi. Holland-Dutch East India line, longest mail and passenger route in existence at present, K. L. M. radio equipped airplanes touch three continents; equipment is illustrated and described.

AMPLIFIERS. Tube Amplifier Equivalent Parallel Circuit, G. D. Robinson. *Electronics*, vol. 3, no. 3, Sept. 1931, p. 105, 1 fig. It is shown that parallel substitution for simple series circuit is merely simplification of general parallel equivalent circuit, in which internal plate resistance, load, and grid-to-plate reactance are all treated as being in parallel.

CONTROLS. An Analysis of the Series Type Mixing Control, L. B. Halliman, Jr. *Radio Eng.*, vol. 11, no. 9, Sept. 1931, pp. 17-18, and 35, 8 figs. Discussion of various control systems and faders for use in radio broadcasting, talking motion picture and phonograph recording work, when using more than one microphone to obtain more natural and higher quality of reproduction or to have level from each microphone under absolute control and to have each control independent of other.

OSCILLATORS. Quartz Oscillator Wave Constants, E. G. Watts. *Radio Eng.*, vol. 11, no. 9, Sept. 1931, pp. 23-26, 2 figs. Attempt to coordinate results of prominent investigators in field, presenting in summarized form data on constants of longitudinally and transversely vibrating modes, in so far as it is accurately known.

RECEIVING APPARATUS—AUTOMATIC CONTROL. Use of Vacuum Tube Operated Relay to Control Blasting in Radio Receivers, B. Ephraim. *Radio Eng.*, vol. 11, no. 9, Sept. 1931, p. 27, 2 figs. Diagram and analysis of simple relay control system in audio circuit.

RECTIFIERS. The Design of Power Rectifier Circuits, M. McDonald. *Wireless Engr.*, vol. 8, no. 97, Oct. 1931, pp. 522-531, 8 figs. Methods of calculating effect of resistance in circuit and also effect of variation in size of tank condenser; practical examples are given.

WAVES. The Expanding Short-Wave Spectrum. *Electronics*, vol. 3, no. 3, Sept. 1931, p. 91. Compilation of known data on present and future radio channels on waves from 30,000 to 7½ cm. is given on chart.

Railroads

ELECTRIFICATION. Railway Electrification—An Alternative Proposal. *Ry. Gaz.*, vol. 55, no. 10, Sept. 4, 1931, p. 298. Finance of main-line electrification; economical alternative; scope for reduced rates; advantages of oil-electric traction.

SIGNALS—INTERLOCKING. Electric Interlocking Installed in Birmingham, Ala., L. R. Stahl. *Ry. Signaling*, vol. 24, no. 9, Sept. 1931, pp. 309-311, 7 figs. Design, construction, and operating details of 47-lever plant at crossing of three roads; simplified track and signal plan of Birmingham plant.

SUBSTATIONS. Mobile Railway Substations. *Elec. Rev.*, vol. 109, no. 2808, Sept. 18, 1931, p. 427, 3 figs. Truck-mounted mercury-vapor rectifying outfits for Italian state railways for three-phase 16 2/3-cycle system direct current at 3,000-v. contact-wire pressure for Benevento-Foggia and other lines.

TRAIN CONTROL, AUTOMATIC. Automatic Train Control on the Southern Railway. *Engineer*, vol. 152, no. 3950, Sept. 25, 1931, pp. 332-333, 8 figs. In Strowger-Hudd system permanent magnets and electromagnets are used to operate receivers carried by locomotive, which cause whistle to be blown and continuous brake to be applied as required; receivers are actuated by inductors, of which there are usually three.

Railroad Crossings

SIGNALS AND SIGNALING. Crossing Protection Signals on the Milwaukee Road. *Ry. Signaling*, vol. 24, no. 9, Sept. 1931, pp. 316-318, 9 figs. Older type of protection replaced by flashing-light type with rotating stop disk; operating conditions; plan showing location of signals in Oconomowoc; control of signals.

Rectifiers

D-C. Conversion Equipment, A. M. Garrett. *Nat. Elec. Light Assn.—Bul.*, vol. 18, no. 9, Sept. 1931, pp. 595-598, 4 figs. Report of electric machinery subcommittee of Electrical Apparatus Committee; enclosed converters; method of determining adequacy of soldered joints; new developments in conversion equipment; total number and capacity of rectifier sets installed in United States and Canada; telephone interference; high speed switching for rectifier.

Relays

Electrical *versus* Mechanical Devices Used in Control and Regulation Engineering, J. F. Shadgen. *Iron and Steel Engr.*, vol. [illegible], no. 9, Sept. 1931, pp. 378-382, 12 figs. Corrective devices used in art of regulation; regulating valves; regulating dampers; rheostats; solenoids; brakes and clutches; characteristics of fluid amplifying devices; characteristics of electric amplifying devices. Before Am. Iron and Steel Elec. Engrs.

Rolling Mills

ELECTRIC EQUIPMENT. Electrical Equipment of the Slabbing and Hot Strip Mills at the Wheeling Steel Corporation's Steubenville Plant, J. Farrington and H. A. Winne; *Iron and Steel Engrs.*, vol. 8, no. 7, July 1931, pp. 324-336, 16 figs. Outstanding mill installations of recent years are 45 in. reversing Universal slabbing mill and continuous hot strip mill at Steubenville, Ohio, plant of Wheeling Steel Corp.; complete electrical installation, starting with incoming 66,000-volt power lines, carrying through Ohio Power Co.'s Fort Steuben substation, Wheeling Steel Corp., outdoor substation on to 60 in. mill motor room and main auxiliary drives.

ELECTRIC DRIVE. Electric Power is Regenerated by New Roll Train Drag, A. J. Whitcomb. *Steel*, vol. 89, no. 16, Oct. 12. 1931, pp. 31-33, 5 figs. Installation combining successful regeneration of electric power with production of dragging torque which prevents back lash in sheet mill in Detroit districts; power regenerated is 540,000 kw-hr. and represents saving of $5,400 per year.

Substations

AUTOMATIC. Electricity in Limestone Mining, F. P. Brightman. *Eng. and Min. Jl.*, vol. 132, no. 5, Sept. 14, 1931, pp. 205-206, 4 figs. Details of equipment and operation at double-unit, completely automatic substation installed at Pittsburgh Limestone Co.'s Buffalo Creek mine, near Worthington, Pa., to supply direct current to mine haulage system and for general use in mining operations; synchronous motor-generator sets were selected on account of greater flexibility in control of d-c. voltage and independence of fluctuations of d-c. system voltage which affect d-c. voltage when converters are used.

DESIGN. What a Well-Built Substation May Be. *Elec. World*, vol. 98, no. 14, Oct. 3, 1931, p. 612. Zanesville (Ohio) substation of Ohio Power Co., subsidiary of American Gas & Electric Co. is representative of best and most recent of today's electrical engineering practises, and includes in its design not only features of economy, reliability, safety and ease of operation but also attractive appearance.

Switchboards

Features of Modern Switchboards, E. G. Bern. *Power Plant Eng.*, vol. 35, no. 17, Sept. 1, 1931, pp. 897-899, 4 figs. Evolution has almost extinguished resemblance between earliest and latest switchboards; unit principle of design.

Switches

Elimination of the Disconnecting Switch Hazard, J. Auchincloss. *Power Plant Eng.*, vol. 35, no. 18, Sept. 15, 1931, p. 938, 2 figs. Methods illustrating impossibility of opening disconnecting switch until oil circuit breaker has first been opened; protection afforded by magnetic lock on mechanism of disconnecting switch which is controlled by auxiliary switch on mechanism of circuit breaker.

The Minatro—A New Idea in Control Switch Design, A. J. A. Peterson. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, pp. 508-510, 6 figs. Control switch requiring only 5 sq. in. of switchboard panel space, using toggle switches for quick make and break contacts, handling 125 volts directly and that can be mounted or dismounted as unit; neat appearance; it is result of deliberate attempt to design switch for specific purpose without regard for precedent or convention.

Telephone

CIRCUITS. Four-Wire Telephone Circuits, G. C. Crawford. *Bell Laboratories Rec.*, vol. 10, no. 1, Sept. 1931, pp. 6-12, 8 figs. Advantages and characteristics of four-wire circuits; details of 44 A-1 repeaters for use in 4-wire circuits; wiring diagram of repeater.

Television

APPARATUS—OPERATION. The Practical Operation of a Complete Television System, A. B. DuMont. *Radio Eng.*, vol. 11, no. 7, July 1931, pp. 33-36, 8 figs. Technical description of Jenkins system of television now in operation.

Transformers

FOUR-WINDING. Four-Winding Transformers. *Engineer*, vol. 152, no. 3948, Sept. 11, 1931, pp. 304-305, 4 figs. Three-phase, 50-cycle transformers with four windings built by Oerlikon Co. for Ryburg-Schwoerstadt Power Supply Co., Rheinfelden, Switzerland; capacity of each of windings is 32,500 kva. while continuous overload capacity is 35,000 kva.

INSTRUMENT. A Through Type Current Transformer and Amplifier for Measuring Alternating Currents of a Few Milliamperes, W. B. Kouwenhoven. *Rev. Sci. Instruments*, vol. 2, no. 9, Sept. 1931, pp. 541-548, 2 figs. Transformers and vacuum-tube amplifiers constructed for experimental study of effects of electric shock for measurement of current actually passing through vital organs; wiring diagram and characteristics of instrument.

PARALLEL OPERATION. Balance Coil or Reactor for Paralleling Transformers, E. C. Wentz. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, pp. 526-529, 8 figs. If transformers to be paralleled are different in turns ratio, balance coil is indispensable; balance coil must also be used when secondaries of two transformers are to be paralleled, and primaries are supplied from different sources; reactors, though more limited in application, are more easily installed and have advantage of simplicity.

SPARE WINDING. Grounding Transformer Bank Supplies Station Energy. *Elec. World*, vol. 98, no. 14, Oct. 3, 1931, pp. 612-613, 2 figs. To serve as spare source of energy for station service equipment, 2,000-kva., 33,000/13,200/2,300-volt grounding transformer bank has been provided with third winding for full-capacity output of 2,300 volts at Gilbert station of Associated Gas & Electric System at Holland, N. J.; wiring diagrams are given.

Transmission Lines

HIGH TENSION—ANALYSIS. Transmission Line Analysis Indicates Ruling Tendencies, E. B. Kurtz and J. A. Douglas. *Elec. World*, vol. 98, no. 13, Sept. 26, 1931, pp. 553-555, 10 figs. Graphical determination of relations between major design values of present-day electric power transmission lines was undertaken in belief that study of large number of lines would reveal general laws governing recent design practise; analysis is based on table on "Engineering Details of Transmission Lines in United States" published by *Electrical World* in 1929, giving engineering details of 877 high-voltage transmission lines.

HIGH TENSION—INSPECTION. Methods and Procedures for Inspection of Materials Used on Overhead Lines. *Nat. Elec. Light Assn.—Pub.*, no. 150, Aug. 1931, 38 pp., 1 fig. Procedures which if followed in inspecting conductors, poles, insulators and hardware, should result in obtaining satisfactory material; methods are intended to cover more important requirements in most practical way and to indicate common-sense interpretations of various specification requirements.

HIGH TENSION—RELAYS. Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, pp. 535-538, 11 figs. Relay scheme for parallel line protection is outlined; various diagrams of connection are given.

Vacuum Tubes

Patents Relating to Electronic Devices in Industry. *Electronics*, vol. 3, no. 3, Sept. 1931, pp. 92-93, 5 figs. Three patents granted by United States Patent Office are described; Langmuir patent for connecting light-sensitive cell and vacuum tube; Logan method of using light-sensitive cell for regulating flow of gas in sulphuric acid manufacture; Logan patent by which light-sensitive cell is controlling shaft revolutions; Nakken patent for combination of light-sensitive surface and triode.

ELECTROCHEMISTRY. The Electron Goes to Work in Industry, J. A. Lee. *Electrochem. Soc.—Trans.*, vol. 59, 1931, pp. 229-236, 1 fig. In electrochemical industries vacuum tube has already been adapted for several purposes and it has been suggested for many others where increased accuracy of measurements and production efficiency are important; outline of various uses for tubes and photoelectric cells.

LABORATORY USES. Electronic Tubes in the Laboratory. *Electronics*, vol. 3, no. 3, Sept. 1931, pp. 114-115, 4 figs. Symposium consisting of four short articles; Life Test for Condensers, H. W. Houck; Circuits for Light Sensitive Cells; Piezoelectric Measuring Devices, J. Lluge, H. E. Linckh, R. A. Webster, S. L. Brown and S. Harris; Vacuum Tube Control for Electric Balances, F. S. Eastman.

MEASUREMENTS. A New Method of Measuring Vacuum Tube Characteristics, J. R. Barnhart. *Radio Eng.*, vol. 11, no. 7, July 1931, pp. 30-31, 4 figs. Method of determining dynamic mutual conductance, amplification factor and plate resistance was evolved mathematically from consideration of properties of self-biased tube; equipment used consists of source of filament current, source of plate current, galvanometer and suitable resistances.

PRESSURE INDICATORS. A Cylinder Pressure Indicator, L. R. Quarles. *Elec. Jl.*, vol. 28, no. 9, Sept. 1931, p. 519, 2 figs. Newly developed grid-glow tube device for testing internal-combustion engines makes possible continuous and visible indication of pressures in cylinders.

TELEVISION. A New Modulation Tube for Television, H. F. Dalpayrat. *Radio Eng.*, vol. 11, no. 7, July 1931, p. 37, 1 fig. New mercury vapor arc tube described has very large output of modulated light and shows great possibilities.

TESTING. Vacuum Tube Life Tests, J. N. Fuller and P. W. Charton. *Radio Eng.*, vol. 11, no. 7, July 1931, pp. 21-23, 2 figs. Test conducted to determine life span of product in question, consisting in subjecting it to continuous operation simulating actual usage conditions until it wears off and becomes unsatisfactory; for vacuum tube this means until one or more of its characteristics varies beyond specified limits.

VOLTMETERS. Vacuum Tube Voltmeter of High Sensitivity, H. J. Reich, G. S. Marvin and K. A. Stoll. *Electronics*, vol. 3, no. 3, Sept. 1931, pp. 109-111, 6 figs. For larger a-c. voltages or for d-c. voltages peak type of vacuum tube voltmeter can be used, but as ordinarily constructed, using three-element tube, sensitivity is rather poor; in order to find more suitable tube, survey was made of more recent types of tubes; results of this work have made possible development of sensitive portable instrument described.

Voltage Regulators

A Non-Contact Voltage Regulator *Elec. Rev.*, vol. 109, no. 2802, Aug. 7, 1931, p. 211, 4 figs. "No contact" equipment resembles hydraulic regulator used for water turbines; apparatus acts instantaneously and produces very high operating torque.

Watthour Meters

TESTING. Manual Switching Eliminated in Rotating Standard Testing. *Elec. World*, vol. 98, no. 13, Sept. 16, 1931, p. 542, 1 fig. Great sensitivity, combined with stable operation, is claimed for vacuum tube and switch device for timing rotating standards, developed in meter department of Puget Sound Power & Light Co., according to recent report of N.E.L.A. meter committee; nervous and muscular coordination of tester do not affect test when this equipment is used.

Welding

ARC—ATOMIC HYDROGEN. Hydrogen Welding Now Automatically Controllable, S. Martin, Jr. *Elec. World*, vol. 98, no. 13, Sept. 26, 1931, p. 561, 1 fig. Welding automatically with atomic hydrogen flame presents problem of maintaining definite size of flame in fixed plane between two slowly consuming tungsten electrodes; relation of fringe of flame and work is fixed mechanically; push-button control scheme for automatic hydrogen welding, is given.

ARC—ELECTRODES. Future Development of Electrodes, T. E. Jerabek. *Welding*, vol. 2, no. 9, Sept. 1931, pp. 623-625, 3 figs. Development of thicker coatings; automatic electrodes; physical composition of electrode; possibilities of electrodes ¾ in. in diam. operating at 1,000 amp.

CHROMIUM-NICKEL STEEL. How to Weld the Chromium-Nickel Steels, S. C. Alexander. *Welding*, vol. 2, no. 8, Aug. 1931, pp. 514-517, 7 figs. Practical applications illustrate welding technique; effect of temperature on physical properties of Nirosta KA2 or "18 and 8" chromium-nickel steel based on short time test.

HOUSES, STEEL FRAME. Arc Welded Steel Residences. *Constructor*, vol. 13, no. 9, Sept. 1931, pp. 26-27, 5 figs. Features of arc welded steel frame residences in Mamaroneck, N. Y., and at Shaker Heights, Cleveland, Ohio; method of using "Battledeck" steel flooring in connection with welded steel frame residence construction; method of fastening wood sleeper to battledeck floor construction.

NICKEL. British Practise in the Welding of Monel Metal and Pure Malleable Nickel, N. C. Marples. *Am. Welding Soc.—Jl.*, vol. 10, no. 3, Mar. 1931, pp. 14-17, 6 figs. Applicability of welding methods for monel metal and pure nickel sheet, with reference to thickness; oxygen control, fluxes, use of filter rod, automatic electric seam welding.

STEEL. Analysis of Steel for Welding, W. E. Stine. *Metal Progress*, vol. 20, no. 2, Aug. 1931, pp. 91-94, 5 figs. Investigations at Lincoln Research Laboratory to determine welding characteristics for metallic arc welding with bare or washed electrodes; metallic arc welding with special electrodes; carbon arc welding with completely shielded arc; Lincoln-Stine equilibrium curve showing relation between aluminum, silicon, and manganese in carbon steels to produce best welding characteristics.

STEEL STRUCTURES. Arc Welding Joints in Steel Structures, R. W. VanKirk. *West. Machy. World*, vol. 22, no. 9, Sept. 1931, pp. 405-406, 2 figs. Development of arc welded structural joints; permissible unit stresses; advantages of electric welding; inspection.

Welders

TRAINING. Training Welders for Industrial Work, C. D. Moore. *Welding Engr.*, vol. 16, no. 7, July 1931, pp. 37-38, 4 figs. Need of practical experience of welders in addition to school training; illustrations show various conditions under which welder is required to work.

Welds

STRESSES. Stress Relieving Welded Joints, R. E. Kinkead. *Welding Engr.*, vol. 16, no. 7, July 1931, pp. 25-28, 14 figs. Nature of residual strains in steel due to temperature change; series of tests of residual stresses in welds and methods of removal.

Wheatstone Bridges

ELECTROLYTES. A Bridge for the Measurement of the Conductance of Electrolytes, P. H. Dike. *Rev. Sci. Instruments*, vol. 2, no. 7, July 1931, pp. 379-395, 4 figs. Bridge which has been designed to give higher degree of accuracy than has previously been attainable in measurements of this type, and with greater convenience of manipulation and of interpretation of results.

Industrial Notes

Unemployment Relief Plan of I-T-E Circuit Breaker Company.—It is announced that two per cent of the gross sales of the I-T-E Circuit Breaker Company, Philadelphia, for the next five months will be donated to the relief organizations of the communities in which those sales originate. A special fund of $25,000 has been deposited with the Philadelphia Trust Company from which, within ten days after receipt of each order, a check will be drawn for the relief work. No order for less than fifty dollars will be included in this relief plan. These voluntary donations all over the country will be in addition to the Company's donations for local relief. It is the hope of the I-T-E Circuit Breaker Company that other members of the electrical industry as well as of other industries, may be led to adopt this plan or a modification of it for supplying the money needed to ameliorate the condition of the nation's unemployed.

New Frequency Monitor for Broadcasting Stations.—Announcement has been made that the General Radio Company, Cambridge, Mass., has just completed development of a new frequency monitoring equipment, which will enable broadcasting stations to check their frequencies to within ± 50 cycles per second of the assigned value in accordance with the requirements of General Order No. 116 of the Federal Radio Commission. A preliminary descriptive bulletin of this equipment is available.

A New Transmission Drive.—The American Engineering Company, Philadelphia, has developed a flexible electro-hydraulic transmission, delivering any speed from zero to the maximum of the unit. One end of the transmission is connected to an electric motor or prime mover rotating at a constant speed. From the other end intermediate, smooth speeds can be obtained from maximum to stop. Among the other advantages claimed for the new development are that the direction of rotation can be changed from one direction to the opposite direction almost instantly. Controls are available to make the transmission perform a series of operations automatically. The unit is extremely compact and no gears, pulleys, chains or belts are used in construction. It is shock-proof and self-lubricating; an across-the-line starter is all that is needed for control; has a high starting torque; and it is impossible to overload the device. At the present time 5 to 15 hp. units are being manufactured.

New Motor Starter.—The Electric Controller & Manufacturing Company, of Cleveland, Ohio, announces the "No. 1 Type ZEO Across-the-line Explosion-proof Starter," which has been officially approved by the Underwriters for Class 1, Group D hazardous locations. The enclosing case is strong and tight enough to prevent the transmission of any flame that may occur within the case to surrounding atmosphere, and the flanged joint between the upper and lower parts of the case is of sufficient length to cool any gases formed within before they can come in contact with the surrounding atmosphere. The contactor mechanism and overload relays are mounted on a slate base which is removable from the case. The main contacts and overload relay contacts are oil immersed and all working parts are kept well lubricated and protected from corrosion by capillary attraction of the oil. The maximum ratings of this starter are 5 hp., 110 volts, and 10 hp., 220, 440 and 550 volts.

Agency Appointments of Meter Devices Company.—J. G. Corrin, 140 North Sycamore Avenue, Los Angeles, has been appointed sales representative in California for the Meter Devices Company, Canton, Ohio. The Wagner Peterson Corporation, 535 Clifton Street, Portland, was recently appointed to represent the Meter Devices Company in the states of Oregon and Washington.

Kearney Corporation and Chance Company Merge.—It is announced that James R. Kearney Corporation, St. Louis, has combined with the Chance Company, Centralia, Mo., manufacturers of pole anchors. The combination makes it possible to supply every type of anchor for construction requirements from a single and centrally located manufacturer. The Kearney anchors include the 4-in-1 expansion anchor, steel rod screw anchor, pipe rod screw anchor and "No-Rench" screw anchor; the Chance anchors include the 2 and 4 way expansion anchor, pyramid "cone" anchor, never-creep plate anchor and steel screw anchor.

Trade Literature

Distribution Connectors.—Bulletin 38-T. Describes distribution connectors for copper and aluminum conductors, hot line clamps and insulated sticks. Delta-Star Electric Company, 2400 Block, Fulton Street, Chicago.

Portable Instruments.—Bulletin 160, 12 pp. Describes Roller-Smith portable instruments—ammeters, voltmeters, volt-ammeters, single and polyphase wattmeters, frequency meters, power factor meters, transformers and multipliers. Roller-Smith Company, 12 Park Place, New York.

Motors.—Bulletin 210, 4 pp. Describes type "T" two-pole Reliance d-c. motors; semi-enclosed and fully-enclosed construction; pulley or sleeve bearings; in sizes up to 3 horsepower., 1,750 r.p.m. Reliance Electric & Engineering Company, Ivanhoe Road, Cleveland.

High Tension Fuses.—Bulletin 39, 8 pp. Describes Pacific Electric distribution fuse cutouts, type EM fuse supports and type EM-1 fuse switches with type EX fuse holders. Pacific Electric Manufacturing Corporation, 5815 Third Street, San Francisco, Cal.

Circuit Breakers.—Bulletin GEA-959C, 12 pp. Describes General Electric type FKR-155 oil circuit breakers, 7,500 and 15,000 volts—400 to 3,000 amperes, triple pole—single throw. This type constitutes a complete line of indoor breakers for moderate and heavy duty service. General Electric Company, Schenectady, N. Y.

Motors.—Bulletin 20516, 2 pp. Describes new, single-phase Westinghouse motors, 2 to 7½ horsepower. Because of their excellent torque characteristics these motors have extensive applications on pumps, compressors, ventilating fans, blowers, farm machinery, and wherever high starting and high accelerating torques are necessary. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Asbestos Insulated Wires and Cables.—Bulletin 10-A, 30 pp. Describes Rockbestos insulated wires and cables, designed and built to withstand extremely high temperatures, oils and greases, the majority of acid fumes and vapors, etc. Specifications and descriptions are given for solid, coarse and flexible stranded cable with Rockbestos insulation from 600 to 7,500 volts; also switchboard wire, multi-conductor control cable, lead sheath control cable, locomotive cab cord, etc. Rockbestos Products Corporation, New Haven, Conn.

Circuit Testers.—Supplement, 2 pp. Describes Roller-Smith circuit testers. This low priced instrument can be used to ascertain if there is an electrical circuit existing between conductors applied to the terminals of the instrument and, secondly, it enables the user to read the resistance of the circuit under test. The HTD circuit tester is recommended by the maker for use in preference to magnetos and a-c. bell-ringing devices because of its accuracy of indications under all conditions and its lightness and compactness as well. Roller-Smith Company, 12 Park Place, New York.
